

st figure would correspond with a human dose of 180 g, that ill-effects need not be feared in therapeutic experiments in man

It should be noted that yeast does not actively favour necrosis it is merely poorly protective. Yeast is a good source of choline, and it possibly contains other unknown lipotropic principles (Gyorgy and Goldblatt, 1939, Rich and Hamilton, 1940). Yeast may therefore be expected to be a useful remedy in most forms of fatty infiltration of the liver due to dietary imbalance. Some of the B vitamins, particularly biotin, favour the deposition of fat in the rat's liver, this type of fatty liver is resistant to choline but responds to lipocain or inositol. In fact, the relation of the B vitamins to cirrhosis and necrosis of the liver has not yet been completely elucidated. Growing rats and mice have a high rate of metabolism, which affects their vitamin B requirements, and in larger animals the action of the B vitamins on the liver may be different (Fouts, 1943). On the present evidence it seems a justifiable conclusion that no ill effects on the liver are likely to accrue from massive dosage with yeast or other sources of the vitamin B complex in hepatic disease in man.

Diet and Resistance to Hepatitis

In view of the gross damage to the liver which may result from dietary defect it is not surprising that lesser deficiencies may impair the resistance of the liver to injury by poisons. It has been known for many years that animals which have been starved or been fed on an excessive proportion of fat develop fatty infiltration of the liver, and with this goes a diminished resistance to a number of hepatic poisons. It has also long been known that a damaged liver contains little glycogen, and that animals fed on high-carbohydrate diets are in general less susceptible to drugs which produce accumulation of fat in the liver than are those given high-fat diets (Rosenfeld, 1903). Not only does a high carbohydrate intake give some protection against poisoning by chloroform and phosphorus but it is also of value in the prevention of hepatic damage following experimental ligation of the common bile-duct, operation of Eck's fistula, partial hepatectomy, and experimental mushroom poisoning (Soskin and Hyman, 1939).

For carbohydrate to be effective it is probably necessary that glycogen should be deposited in the liver, that fat should be displaced, and that the ingested carbohydrate should spare the body stores of protein. It is an unfortunate error to think that the mechanical displacement of fat by glycogen is the whole story. The truth is rather that carbohydrate is the fuel for the hepatic cell in its work of fat transport, protein synthesis, and detoxication. The great value of carbohydrate may well be that it spares protein. Carbohydrate is not entirely comparable to the petrol in the internal combustion engine, as it may be used to neutralize poisons by forming conjugates with them, but its action is mainly as a source of energy which is quickly consumed. Carbohydrates cannot protect the liver unless the requirements of protein metabolism and total calories are satisfied. If these precautions are not observed an unbalanced carbohydrate regimen may actually favour the development of necrosis (Craven, 1931).

Attention was first concentrated on the part played by protein in maintaining the resistance of the liver when Davis and Whipple (1919) demonstrated that not only carbohydrate but also protein would protect the starved dog against chloroform poisoning. Much of the subsequent work of Whipple and his group has been done with dogs depleted of protein by special diets and sometimes by withdrawal of plasma as well. They have shown that injury to the liver from chloroform increases as protein stores decrease, and that a protein meal before anaesthesia is

beneficial (Miller and Whipple, 1940). They demonstrate that the sulphur-containing amino acids, methionine and cystine, are the specific protective factors and that methionine is more effective than cystine. Finally Brunschwig and his co-workers (1945) showed that equal protection was given by the non-nitrogenous compound thioglycollate, the only common factor was simple sulphhydryl group. While chloroform damaged the liver of the dog, with the organic arsenical the dog must first be depleted of protein, or the animal will die from the other toxic effects of the arsenic before the liver is attacked. Here again the protective action of protein has been demonstrated and traced to the methine level.

There are fewer experiments on the resistance of animals with choline deficiency, presumably because it has so long been known that the fatty liver is vulnerable and also because fatty infiltration may slowly disappear without specific treatment. Best and his co-workers (Best *et al.*, 1935, Barrett, 1939) have shown that when rats are maintained on a diet low in lipotropic factors and then poisoned with phosphorus or carbon tetrachloride the addition of choline to the diet has no effect on the degree of fatty infiltration or damage to the liver, but it speeds up the rate of disappearance of fat from the liver in the recovery phase.

This brings us to the time factor in protection experiments, which is of special importance when we come to apply the results to man, for man can rarely take action till exposure has occurred. Ethionine will give complete protection against chloroform if administered shortly before anaesthesia. It will give partial protection three to four hours after anaesthesia, but protection more than four hours after anaesthesia (Miller and Whipple, 1942). With mapharside protection has been obtained by the oral administration of methionine 24 hours before the injection of the arsenical, but only partial protection with intravenous injection just prior to mapharside injection. The latter failure may well be due to too small a dose—1 g per dog, instead of the 3 g used in the other experiments (Goodell *et al.*, 1944). Most of the work so far recorded has dealt with animals on defect diets. A variety of food factors, including methionine, glucose, para-amino-benzoic acid (Sandground and Hamilton 1943), liver extract, and sodium xanthine (Barrett *et al.* 1938), will enhance the normal resistance against certain poisons, but there is no evidence that choline can act in this way.

Dietary Treatment of Experimental Hepatitis

The lipotropic action of protein and the antinecretic action of the protein sulphur leads to expect that protein would be of great value in the treatment of hepatic injury, and at first sight it is puzzling to find that apparently it is not. Treatment is a different thing from prophylaxis. Much of the experimental assessment of therapy has been carried out on animals poisoned with carbon tetrachloride. Some of the factors affecting recovery from carbon tetrachloride poisoning have been carefully studied by Lamson, Minot and Robbins (1928). They found that dogs treated with carbon tetrachloride more commonly died from acute necrosis when they were on a lean meat diet than on a mixed diet containing bone meal. The addition of calcium to the preceding diet of lean rat reduced the mortality to normal. Acute necrosis after carbon tetrachloride in man is more common in children and in the malnourished, and they suspect that this is due to calcium deficiency. Lamson (1930) recalled that Whipple had found that a high-carbohydrate diet protects dogs against poisoning by chloroform, and he pointed out that such a diet usually takes the form of bread and milk, which is high in calcium and low in meat.

The high-calcium diet does not diminish the liver damage it merely diminishes the symptoms. These symptoms are attributed to a high blood level of guanidine, which leads to severe hypoglycaemia and peripheral circulatory failure. Calcium salts neutralize the guanidine, and glucose repairs the hypoglycaemia. On this argument death in hepatitis may be due to incomplete metabolites or products of autolysis, and if these can be neutralized spontaneous recovery may occur. Lamson (1930) further showed that the feeding of meat to susceptible animals causes a tremendous increase in blood guanidine, with a fall in blood sugar, tetany, convulsions, gastro-intestinal haemorrhage, and death. Guanidine has always been something of a will-o'-the-wisp in metabolic diseases, and this line of research has seemingly been held up by the necessity for studying its pharmacology. Certainly Bollmann and Mann (1936) found no excess of guanidine in the experiments described in the next paragraph. The relief of the symptoms of acute necrosis of the liver by calcium recalls recent work on adenosine triphosphate, which is believed to be an important factor in shock from tissue damage. Adenosine triphosphate is potentiated by magnesium, and magnesium and calcium are physiological antagonists (Green and Stoner, 1944).

Bollmann and Mann (1936) have experimented with diets in a variety of hepatic injuries in dogs. After performance of Eck's fistula a condition known as meat intoxication is liable to develop, though the name perhaps exaggerates the extent to which it is due to meat. After complete obstruction of the bile-duct a diet rich in carbohydrate becomes increasingly necessary for the maintenance of the animal. After two or three months a diet exclusively of meat will prove fatal within a week, but if the diet is high in carbohydrate life may be prolonged for at least a year. The animals are extraordinarily prone to develop ascites after feeding on meat. The active substance which induces ascites is probably not protein, because milk protein does not favour ascites, whereas meat extract produces results which are even more striking than those of meat. Comparable results were obtained with 16 dogs, each of which was given 10 ml of carbon tetrachloride daily by mouth. The four dogs that were given a high-fat diet all died within three weeks. Of the four dogs that were given an entirely meat diet, two died within three months, and the other two had ascites. The remaining eight dogs, which were given mixed diets, were all alive at the end of three months, though the four which had received their protein in the form of meat were not in such good shape as those which had received milk.

Bollmann (1943) has more recently determined the time of survival of rats which were exposed to carbon tetrachloride vapour for 30 minutes three times a week. On the ordinary mixed diet the rats lived from 36 to 42 days. In a second group of experiments half of this diet was replaced with isocaloric values of cracker-meal and sucrose, meat, or lard. Expressing the normal survival time as 100, the investigators obtained the following figures for survival: carbohydrate, 146; protein, 100; fat, 91. In another series three-fourths of the mixed diet was replaced with isocaloric values of the above foodstuffs, and the protective values were now: carbohydrate, 205; protein, 104; fat, 59.

Dietary Cirrhosis of the Liver in Man

A low intake of protein with insufficient supply of the vitamin B complex, including choline, is a prominent feature of the diet of persons addicted to alcohol. In the earlier stages of alcoholism fatty infiltration of the liver is said to occur, and there is a growing tendency to affiliate alcoholic cirrhosis with the cirrhosis produced in animals by lack of lipotropic factors. But alcohol is not the only

cause of cirrhosis in man, nor is it the commonest. All writers on tropical pathology have laid stress on the frequency of liver cirrhosis with ascites among native races where the influence of alcohol can be discounted (Manson Bahr, 1945).

References to cirrhosis in India, Ceylon, and China are given in Ratnoff and Patek's (1942) review. A striking feature of tropical cirrhosis is the high incidence in children and the relative frequency of recovery, even when the disease has reached the ascitic stage. The hepatic lesions have generally been attributed to the interplay of malnutrition and infection, and no clear line has been drawn between portal cirrhosis and postnecrotic fibrosis. In Jamaica where infantile cirrhosis of the liver is common, it has been noted particularly in the children of mothers who generally being unmarried, have to support themselves and their babies by working in the urban areas or on plantations or elsewhere. Breast-feeding, therefore, is scanty, and the infant's diet consists mostly of carbohydrate—e.g. arrowroot, cereal gruel, or even sugar and water. There is a suggestion that the disease is less frequent in fishing villages, where protein intakes may be higher (McFarlane and Branday, 1945; Platt, 1946).

Throughout Africa there occurs a condition known as infantile pellagra, or "kwashiorkor." It is found in infants and to a less extent in adults, who are fed on bulky vegetarian low-protein diets, and it is characterized clinically by oedema, pellagrous skin lesions, steatorrhoea, and macrocytic anaemia (Trowell and Muwazi, 1945). A necropsy or biopsy an extreme degree of fatty infiltration of the liver is found (Smith, 1943), and there is no doubt that this fatty liver is eventually followed by cirrhosis. Gill (1944) noted that cirrhosis and cancer of the liver are especially prevalent among South African negroes, and showed that cirrhosis and necrosis of the liver occurred in rats who were fed on the South African native diet. It concluded that recurrent attacks of malnutrition result in progressive hepatic damage. Subsequently the Gill (1945) showed by serial liver punctures of patients that fatty infiltration responded slightly to liver extract and was completely cured by desiccated stomach in a dosage of 10 g a day. It seems unlikely that the lipotropic action of desiccated stomach is entirely due to its choline content. With the technique of liver puncture and sternal puncture, and the introduction of pure factors such as choline, methionine, and folic acid, this whole field is now open to research, and we shall not have long to wait for the first harvest.

Dietary Protection Against Hepatic Disease in Man

It has been believed for many years, and probably with reason, that carbon tetrachloride and arsenicals are most likely to damage the liver when the patient is undernourished, but no precise data are available. Beattie (1943-4) has claimed that during antisyphilitic treatment with arsenical drugs the incidence of liver damage can be reduced significantly and the time of greatest liver damage can be postponed by the administration of casein, glycine, cystine, and methionine. Experiments of this kind are complicated by the virus of homologous serum jaundice and by the reduction of the antiprotozoal activity of arsphenamine by the sulphur compounds.

During the war the low incidence of infective hepatitis in coloured troops and native races was the subject of frequent comment, but less notice was taken of the high mortality they suffered. I have previously mentioned an outbreak in Belgian colonial troops, with a mortality of 4% (Witts, 1944). In 1943 a very high mortality was recorded in a small epidemic among some African labourers in Uganda who were in a state of

nutrition, of 14 cases admitted to hospital, all died¹ Figures on the incidence and mortality of infective hepatitis in India Command during 1944 were collected by Lieut-Col Stuart McDonald¹ These figures showed the usual difference between officers and other ranks In addition they showed that the incidence of jaundice was five times as high in British troops as in Indian troops, but, on the other hand, the mortality was five times as great in the Indians as in the British In the final issue British troops and Indian troops had an equal chance of dying of jaundice There is some evidence that while malnutrition favours bacterial infection it antagonizes infection by viruses (Foster *et al*, 1944) There was a good deal of anaemia and malnutrition among Indian troops^{2,3} One cannot say whether the low incidence in Indians was due to nutritional factors or to previous exposure, but there is a strong suggestion that the relatively high death rate was due to malnutrition

Discussion

A survey of the animal experiments leaves us in little doubt as to the importance of the lipotropic factors and the thio-amino acids to the health of the liver An excessive intake of fat will be harmful to the liver unless it is balanced by a corresponding increase in lipotropic factors, while a high-carbohydrate regimen helps by sparing the reserve stores of protein in the liver and providing easily available energy Proteins supply the essential methyl and sulphhydryl groups, but they may also contain harmful residues which are badly tolerated in acute and chronic liver disease Milk proteins appear to be innocuous in this regard, whereas meat and meat extracts are harmful Choline and lecithin are present in most animal and plant tissues, and the thio-amino-acids are particularly well represented in the proteins of milk

The most important lipotropic factors are those which provide the labile methyl groups for the manufacture of phospholipins, without which fat transport comes to a standstill Excess of fat in the liver leads to a gradual pressure atrophy of the cells and portal fibrosis, and it also accentuates the effect of the many toxic substances which are more soluble in fat than in water Tropical cirrhosis and alcoholic cirrhosis of the liver in man appear to be due mainly to a deficient intake of lipotropic factors, but in both disorders a toxic factor is still suspected by many people

The effects of a deficiency of protein sulphur are more subtle and profound The sulphhydryl groups are attached to the vital enzyme systems in the liver Protein starvation depletes the liver of these sulphur-rich components, and if the process goes far enough the cell must die Methionine and cystine are rapidly incorporated in the depleted liver to make good the deficiency Chloroform and arsenicals disturb the enzyme systems, presumably by combining with or neutralizing the sulphhydryl groups The disturbance is reversible within the first three or four hours of administration of the poison, but after that methionine is no longer effective, and it is clear that viable liver cells are essential for the rapid uptake of methionine Chloroform combines with the sulphhydryl groups to form the non-toxic mercapturic acids The action of arsenicals has been reviewed by Peters, Stocken, and Thompson (1945), who showed that they have a selective action upon the pyruvate enzyme system and that an essential sulphhydryl component of the protein constituent of the system is attacked As a result of their studies they introduced the dithiol compound

BAL, which prevents the toxic action of arsenic and some of the heavy metals if given before the administration of the poison and neutralizes it if the toxicity is not too long established

Himsworth and Glynn (1944b) in their paper on toxic pathic and trophopathic hepatitis have tried to integrate these data, and have suggested that in the final issue hepatic necrosis is always nutritional in origin, always due to a deficiency of essential factors This deficiency may be primary, or it may be secondary to the increased metabolism, the swelling of the liver, and the disturbance of the circulation which result from infection or poisoning of the liver The argument is an ingenious one, but it does not get us very far The liver can be protected against poisons such as chloroform and arsenic by simple chemicals such as sodium thioglycollate and BAL, which act as rather specific antidotes, and it is unlikely that the results obtained with chemical poisons can be transferred without change to the action of biological toxins and viruses In the latter conditions thio amino-acids may act, if they act at all, by providing sulphhydryl groups attached to the appropriate amino acid residue for re-synthesis of essential sulphur proteins which have been inactivated, rather than by neutralizing the noxious agent

[The second lecture, with a list of references, will appear in our next issue]

OBSERVATIONS ON PLAGUE MENINGITIS

BY

D LANDSBOROUGH, M D, B S

AND

N TUNNELL, M B, B S, D T M

(From the General Hospital Chuanchow Fukien S China)

Meningeal involvement in plague has occasionally been recorded, the earliest reports apparently being by the German Indian Plague Commission of 1897 and the Austrian Commission of the same year These are cited by Meyer, Connor, Smyth, and Eddie (1937) in their review of most of the recorded cases of plague meningitis up to that year, while they discuss in detail their own case of "chronic relapsing latent meningeal plague" in California occurring in a patient whose illness began with an axillary bubo Since then further cases have been reported, including one from Uganda by Burton and Hennessy (1940) of 'subacute or chronic plague terminating in haematogenous meningeal infection,' and four cases of plague meningitis complicating bubonic plague from South America by de Villafañe Lastra and Rodeiro (1942)

A particularly rare clinical form—primary plague meningitis—was reported from Dakar by Lafont Lecomte, and Heckenroth (1915) Williams (1934) had a similar case in East Africa, and Lewillon, Devignat, and Schoetter (1940) reported still another from the Belgian Congo These cases like the one described in this paper (Case VIII) presented the common clinical features of meningitis with no bubo formation In China Pollitzer (1946) has observed meningeal involvement in most recent outbreaks In this connexion, therefore, it seems worth while to record eight cases of meningitis in a series of 203 cases of plague admitted to the General Hospital, Chuanchow, South China, during the years 1943-5

Symptomatology

In all except one of our cases (No VIII) meningeal involvement was a complication of pre-existing bubonic plague, symptoms appearing at the earliest on the ninth and at the latest on the seventeenth day of the disease The clinical features closely resembled those of cerebrospinal fever or other acute meningitis Headache, painful stiffness of the neck, and Kernig's sign appeared early and prominently Special symptoms included convulsions (Cases III, VIII), cranial-nerve affections

¹ Unpublished reports to M R C Jaundice Committee

² Report on Investigations on Anaemia in the Indian Soldier from the Anaemia Investigation Team, G H Q, India, 1943-5, New Delhi, 1945

³ Proceedings of the Central Command Conference on Anaemia, held at Agra on Nov 20 and 21, 1944, Benares, 1945

(V), vestibulo cerebellar symptoms (VII), deep coma (II), vasomotor crisis (III). Case VIII, differing from the rest, presented as a pyrexial illness with signs of meningeal irritation, no buboes or other signs being found. There was a coincidental malarial infection. The clinical picture was that of primary plague meningitis.

In lumbar puncture the pressure of the cerebrospinal fluid was as a rule raised, the fluid was cloudy, and in some cases of canary-yellow colour. Other changes resembled those of acute suppurative meningitis: polymorphonuclear leucocytes, increased protein, and disappearance of sugar. *Past pestis* was found in the cerebrospinal fluid in some cases by smear and/or culture. Examination of the blood revealed a marked polymorphonuclear leucocytosis with a few eosinophil granulocytes. All the cases were fatal, the development of internal hydrocephalus being the probable cause of death. The longest period of survival was 29 days from the onset of the disease.

Pathology

Post-mortem examination in one case (No VIII) revealed the following:

Body wasted, no petechial or skin lesions.

Brain. Marked congestion, convolutions and sulci flattened, swelling of all brain tissue. Thick canary-yellow fibrino purulent exudate covering most of the external surface especially the parietal and frontal lobes, temporal pole, Sylvian fissure (spreading along the meningeal artery), base of brain (especially cisterna basalis) covering all the cranial nerves, roof of fourth ventricle (cisterna magna) and the inferior, posterior, and superior surfaces of the cerebellum in the midline. Ventricles, especially the lateral ventricle greatly dilated, with thinning of overlying brain tissue, containing a considerable quantity of yellow slightly turbid fluid—marked degree of internal hydrocephalus. Spinal Cord. Marked congestion, fibrino-purulent exudate less pronounced, but very thick in cauda equina region, matting together cord and nerve roots into a jelly-like mass (cf "dry" lumbar puncture).

Glands. Cervical, axillary, inguinal—reddish brown on section, congested, not enlarged. Spleen. Enlarged soft "septic" spleen, diffuent dark-red jam like cut surface. Liver. Soft slightly congested, noticeable cloudy swelling. Heart. Patchy congestion of epicardium, cloudy swelling of myocardium, fibrinous exudate adherent to contact margins of cusps of mitral valve (fibrinous endocarditis). Lungs. Pink, float in water, pleural surfaces smooth, shiny, patchy congestion. Section revealed general congestion, no consolidation or other pneumonic signs. Kidneys. Pale cloudy swelling of cortex, congestion of medulla. Suprarenal Glands. Pale cortex, moderately distinct pigment zone. Congested medulla. Testis, Epididymis (both sides). Marked congestion, large clear hydrocele on right, small hydrocele on left. Alimentary Canal. Outwardly normal, not specifically examined. Pancreas, Thymus. Pale apparently normal.

The presence of pericardial, pleural, and peritoneal fluids was unfortunately not looked for. In smears from the spleen numerous *Past pestis* were found. Only a few organisms were discovered in the meningeal exudate, while smears from the liver, blood, and fibrinous exudate on the cardiac valve were negative for *Past pestis*.

Diagnosis

The clinical diagnosis of meningitis occurring as a complication of bubonic plague ("secondary plague meningitis") presented little difficulty. Cases in which *Past pestis* was not found in the cerebrospinal fluid (V, VI, VII) were confusing, with the possibility in our minds of the meningeal process being allergic in nature, from initial serum administration. In contrast the other findings in the cerebrospinal fluid especially the absence of sugar, pointed almost certainly to acute infection with pathogenic organisms, these presumably being *Past pestis*. But the whole morbid process in these cases so closely resembled that found generally in the series that there was little reason to doubt their plague nature. Case VIII was not suspected of being plague until culture of the cerebrospinal fluid proved the presence of *Past pestis*.

Treatment

Bubonic Plague.—The mainstay in many cases in 1944 and most cases in 1945 was oral sulphathiazole. The total amount given to each patient was usually over 50 g. Anti plague serum was given in most cases in 1945—40 ml intravenously on each

of the first five successive days. Other treatment was mainly symptomatic.

Plague Meningitis.—With the onset of meningitis sulphathiazole was restarted if it had already been stopped. Anti-plague serum was injected intrathecally in most cases, but it was suspended or withheld in some others (III, IV, VI) where doubt existed at the time as to the nature of the morbid process. Daily lumbar puncture for drainage of the sub-arachnoid space was the rule, while cisternal puncture was performed in some instances if the former was unsatisfactory.

Discussion, with Special Reference to Pathogenesis

The thick fibrino-purulent exudate found over the brain and spinal cord during the necropsy on Case VIII may be presumed to be present in the other cases as well. A similar exudate and distribution were found by Meyer *et al* (1937) in their case but the lateral ventricles were involved while the spinal cord was free. Other similarities included the presence of internal hydrocephalus, the enlargement of the spleen, and the negative findings in the lymph nodes. It is possible that such an exudate would tend to hold back the organisms in its meshes, making difficult their recovery on examination of the cerebrospinal fluid. Negative findings in smear and culture were noted on initial lumbar puncture by Meyer *et al*, and also in another case reported by Rivoalen and Montagne (cited by Meyer *et al*). It is regrettable that no cultures could be made in two of our cases (V, VII) where the smear was negative or doubtful. In Case VII, while no typical plague bacilli were found in the smear, organisms having the appearance of Gram-negative diplococci were present. The possibility of mixed infection with meningococcus or of a secondary invasion of the meninges by this or other member of the *Neisseria* has to be taken into consideration, but such assumptions are not very likely. It is more probable that the organisms seen in this instance were atypical plague bacilli appearing in the "coccoid" form.

The pathogenesis of our own and other cases of primary plague meningitis is difficult to explain. That infection may be due not to invasion through the blood stream but to drop-let infection as in cerebrospinal fever is altogether unlikely. Our patient had not been in contact with pneumonic plague. Conversely, supposing the disease to be a variety of primary septicaemic plague, this latter disease, in China at least, is a rapidly fatal one so that there would be no time for localization in the meninges to take place even if that tendency were present.

Under such circumstances one is led to wonder whether these patients supposed to be suffering from primary plague meningitis have not in fact, at some stage of the disease, a bubo. According to Pollitzer (1945) there are really four varieties of bubonic plague: (1) *pestis minor*, (2) well-marked bubonic infection not leading to secondary septicaemia, (3) bubonic affection followed by secondary septicaemia, and (4) a form characterized by most serious general (septicaemia) symptoms combined with but slight affection of the lymph glands, which obviously have early failed in their attempt to hold back the invading organisms. One can conceive of the gland process being overlooked in this last variety (which incidentally represents a transition stage to primary septicaemic plague), especially if, as happened in our case, the patients are not under close observation throughout the course of the illness, in which circumstances, should meningitis develop, the clinical presentation of primary meningitis is obtained.

Factors which may have influenced the development of meningitis in our cases may thus be tabulated:

Case No	Age (years)	Sex	Localization of Buboes	Time of Appearance of Meningeal Process	Time of Death
I	4	M	Cervical	12th day of illness	12th day of illness
II	26	M	Axillary	9th	22nd
III	40	F		10th	22nd
IV	37	M		16th	19th
V	28	M	Inguinal	12th	14th
VI	16	M		17th	29th
VII	39	F	Epitrochlear and axillary	15th	17th
VIII	1 1/2	M	—	?	17th

So far as these figures go, males seem to be more susceptible, age appears to play no part. It should be noted in this connexion that bubonic plague in China is usually most frequent among young adults. Only two of seven patients with manifest bubonic plague had groin buboes, whereas this localization is present in at least 60% of plague sufferers in general. This is in keeping with the generally accepted view that inguinal bubonic plague is less dangerous than axillary or cervical forms.

The course of illness in all these patients was longer than is usual in plague, and symptoms of meningitis invariably appeared late in the disease. Bearing in mind that (1) the incidence of meningeal complications was much higher among our patients compared with that in other recent outbreaks in China, and (2) we were able to treat many of our patients more energetically than was possible elsewhere, we wonder whether our therapeutic measures did not facilitate meningeal involvement by prolonging the course of illness in those patients who would otherwise have died earlier. The accompanying table, showing the amount of "specific" drugs used in the treatment of plague during the years under review, supports this assumption.

Year	1943	1944	1945
Total No. of plague cases	88	46	69
No. of cases of secondary plague meningitis	1	2	4
Anti plague serum used (ml)			
Total (approx.)	920	1,530	6,330
Per patient	10	33	92
Aspn used (g)			
Total (approx.)	—	390	2,250
Per patient	—	8	33
Sulphapyridine (I.M. suspension) used (g)			
Total (approx.)	327	2	—
Per patient	4	—	—

Note.—Patients dying soon after admission received little or no specific treatment; this considerably lowers the figures for the average amount given per patient.

For the treatment of plague in general, including the prevention of meningeal complications, more effective means are called for. Wagle (1944) found sulphadiazine to be superior to sulphathiazole, our own recent experience agrees with this. Sodium sulphadiazine given parenterally should be still more effective during the initial stages of particularly severe infection. According to Pollitzer (1946), streptomycin is also a most promising new therapeutic agent. Whether and how far it will be advisable to combine these new methods of treatment with serum administration remains to be seen.

Finally, it should be stated that in Chuanchow the shortage of drugs was severe in 1943 and 1944, while the exigencies of wartime China made the clinical and pathological study of these cases obviously incomplete.

Case Reports

[The following is a key to the abbreviations used in the case notes below.—Aspn. Aspiration of bubo, with examination of smear. C. Culture. I.M., I.V., I.Th. Intramuscular, intravenous, intrathecal routes. L.P. Lumbar puncture, thecal drainage (cells in CSF per cmm, G globulin, S sugar). Serum. Anti plague serum. Sulphath. Sulphathiazole. Sulphap. Sulphapyridine. Sulphanil. Sulphanilamide. (These three drugs were given orally unless otherwise stated.) W.B.C. White blood cells per cmm. (N neutrophil granulocytes, E eosinophil granulocytes, B basophil granulocytes, L lymphocytes, M monocytes.)]

Case I Primary Skin Plague, Cervical Bubonic Plague, Secondary Plague Meningitis

Male aged 4, seen 3/7/43, giving a history of one day's high fever, diarrhoea, tender swelling rt side of neck. T 103°F (39.4°C), vesicle with raised dusky areola in rt parietal region, tender enlarged gland in rt posterior triangle. Aspn, *Past pestis* found ++. Parents refused treatment.

Patient admitted 13/7/43. T 105.2°F (40.7°C), P 140, R 40. Toxic, restless, large fluctuant swelling with surrounding brawny oedema whole rt side of neck. Blood WBC 25,500 (N 83%, L 14%, M 1%). The bubo was incised and drained.

Course.—14/7/43. T 105–106°F (40.6–41.1°C), neck rigidity +, Kernig's sign +, L.P. Smear of CSF. *Past pestis* found. Patient died shortly after.

Treatment.—150 ml serum (? route), 4 g sulphanil, 5–6 g sulphap, all before admission. After admission 30 ml serum I.M., 10 ml I.Th., sulphap, 0.5 g I.M.

Case II Axillary Bubonic Plague, Secondary Plague Meningitis

Male aged 26, admitted 12/6/45, with history of one day's high fever, delirium, painful swelling lt axilla. T 104.2°F (40.1°C) not found. Clinically, typical bubonic plague.

Course.—Bubo steadily enlarged, while general symptoms improved. 20/6/45. T 104°F (40°C), P 90, R 24, severe headache, neck rigidity +, Kernig's sign +, L.P. turbid yellow fluid, cells 530. G +, S —. Smear Gram negative bacillus (? *Past pestis*) found (few). C of CSF. *Past pestis* isolated 21/6/45. WBC 11,000 (N 83%, L 16%, M 1%). 22/6/45. T 100°F (37.8°C), P 80. Patient much improved, bubo subsided.

25/6/45. T 103°F (39.4°C), P 90, return of pyrexia. 27/6/45. T 102.6°F (39.2°C), P 90, severe headache, neck rigidity +, Kernig's sign +. 29/6/45. L.P. CSF. G +, S —. Smear organisms not found. Patient becoming comatose. 1/7/45. T 97°F (36.1°C), P 70, R 20, deep coma, pupils dilated, corneal reflexes absent, pulse, good volume. Cisternal puncture. 50 ml cloudy yellowish fluid, cells 280, G +, S —. Smear N predominate, organisms not found. Cisternal drainage repeated same day. 3/7/45. T 99.8°F (37.7°C), P 130, R 30, patient died (pre mortal). T 102°F (38.9°C).

Treatment.—Serum 200 ml (180 ml I.V., 20 ml I.M.) first 5 days onset of meningitis to death, 220 ml (180 ml I.Th., 40 ml I.V.) Sulphath 141 g, sodium sulphath I.M. 2 g.

Case III Axillary Bubonic Plague, Secondary Plague Meningitis

Female aged 40, admitted 23/6/45, with history of 3 days' fever, pain in lt axilla. T 102°F (38.9°C), P 108, R 24, tender swollen gland lt axilla. Aspn not performed. Clinically, typical bubonic plague.

Course.—24/6/45. Another bubo rt groin. 27/6/45. T 100°F (37.8°C), P 84, R 20, general condition improved, buboes larger. 30/6/45. T 104°F (40°C), P 100, R 24, headache, clouded mentality, neck rigidity +, Kernig's sign +, buboes much regressed, non tender. L.P. cloudy fluid, cells 800, G +, S —. Smear N predominate, organisms not found. 2/7/45. T 102°F (38.9°C), P 96, R 24. L.P. CSF. S —, C, no growth. Blood WBC 16,300 (N 91%, B 1%, L 8%).

10/7/45. Sudden attack of profuse sweating, flushing of face (T 95°F (35°C), P 80, R 24). Blood WBC 6,000 (N 80%, L 20%). 11/7/45. Sudden onset of coma, epileptiform convulsions, prolonged and generalized, controlled with general anaesthetic morphine, hyoscine. L.P. canary-yellow fluid under pressure. 12/7/45. T 100°F (37.8°C), P 124, R 30, pulse weakening, marked conjunctival congestion. Patient died. Post mortem cisternal puncture. C of CSF, *Past pestis* isolated.

Treatment.—Serum 320 ml (40 ml I.Th., 280 ml I.V.) in first 10 days. Sulphath 35 g in first 5 days, 54 g from 9th to 17th day. Sulphath suspension 8 g I.M. between 6th and 7th days.

Case IV Malaria, Axillary Bubonic Plague, Secondary Plague Meningitis

Male aged 37, admitted 25/6/45, with history of 3 days' chill high fever, one day painful swelling lt axilla. T 104.2°F (40.1°C), P 140, acute lt axillary adenitis. Aspn. *Past pestis* found ++++. Blood film *Plasmodium vivax* found (few). Spleen enlarged.

Course.—2/7/45. T 100°F (37.8°C), P 84, general condition much improved, bubo very large, marked perianitis. 5/7/45. Bubo softening. 8/7/45. T 103°F (39.4°C), P 96, bubo incised, drained. Blood WBC 26,400 (N 93%, L 7%). 10/7/45. T 103°F, P 100, patient wasted, drowsy, vomiting, facial palsy (no record which side). L.P. opalescent fluid, cells 350, G trace. S —. Smear N predominate, organisms not found. C, *Past pestis* isolated. 12/7/45. T 103°F, P 100, facial palsy disappeared, neck rigidity +. 13/7/45. T 100°F (37.8°C), P 100, comatose, subsultus tendinum, incontinence of urine, neck rigidity ++, Kernig's sign +. L.P. cloudy yellow fluid. Smear *Past pestis* found ++. C, *Past pestis* isolated. Blood WBC 17,000 (N 91%, L 9%). Patient died, with pre mortal rise in T and P.

Treatment.—Serum 200 ml, sulphath 127 g, quinine bisulphate 153 gr (10 g).

Case V Inguinal Bubonic Plague, Secondary Plague Meningitis

Male aged 28, admitted 10/7/44, with history of 4 days' high fever, painful swelling lt groin. T 105°F (40.6°C), P 110, R 40. Small atypical vesicle lt ankle, tender swollen gland in lt groin. Aspn. *Past pestis* found (few).

Course.—16/7/44. T 100°F (37.8°C), P 80, R 25, generally much improved, bubo dull red, indurated, non tender. 20/7/44. T 104°F (40°C), P 100, R 28, severe headache for 2 days.

frequent vomiting, sleepiness, dull mentality, neck rigidity +, Kernig's sign +, lt external rectus palsy Blood WBC 18,400 (N 97%, L 3%) LP canary-yellow cloudy fluid released under high pressure, cells 5,060, G +, S — Smear N predominate, no organisms found Patient passed into coma, with weakening pulse, sluggish pupils, general flaccidity, and died

Treatment—Serum 200 ml (195 ml IV, 5 ml IM) first 6 days, after onset of meningitis, 10 ml I Th, 20 ml IV Sulphath 29 g first 4 days, later 5 g

Case VI Inguinal Bubonic Plague, Secondary Plague Meningitis

Male aged 16, admitted 15/6/45, with history of 2 days' chill, fever, painful swelling rt groin T 103° F (39.4° C), P 120, R 25, tender swollen rt inguinal gland Aspn *Past pestis* found (few)

Course—General condition gradually improved, hubo steadily enlarged 24/6/45 T 103° F, P 90, R 24 commencing suppuration in bubo 27/6/45 T 103° F, P 90, R 24, hubo incised, drained 30/6/45 T 102° F (38.9° C), P 90, R 24, headache, clouded mentality, neck rigidity +, Kernig's sign + LP cloudy fluid, cells 1,000, G +, S — Smear N predominate, organisms not found 1/7/45 Neck more rigid, with head retraction, opisthotonos, deafness

2/7/45 Symptoms improved LP CSF cloudy, yellow, S —, C, no growth Blood WBC 9,000 (N 88%, L 12%) 3/7/45 T 98° F (36.7° C), P 90, R 24, further improvement 5/7/45 T 100° F (37.8° C), P 100, R 24 Patient insisted on leaving hospital, and died about a week later

Treatment—Serum 200 ml IV in first 5 days, onset of meningitis onwards, 60 ml I Th, 20 ml IV Sulphath 52 g in first 4 days, onset of meningitis onwards, 20 g

Case VII Epitrochlear and Axillary Bubonic Plague, Secondary Plague Meningitis

Female aged 39, admitted 28/7/44, with history of 2 days' high fever, painful swelling at lt elbow and lt axilla T 102.4° F (39.1° C), P 104, R 26, acute lt epitrochlear and axillary adenitis with peradenitis Epitrochlear gland aspn *Past pestis* found + Blood WBC 10,400 (N 84%, L 15%, M 1%) Urine moderate albuminuria, few pus cells

Course—Pyrexia maintained, buhoes increased in size, oedema of whole limb down to fingers 9/8/44 WBC 16,900 10/8/44 T 103° F (39.4° C), P 100, R 30, buboes and oedema subsiding Onset of painful stiff neck, headache, marked vertigo, relieved by keeping eyes shut, vomiting Neck rigidity +, Kernig's sign + Eyes fine rotatory nystagmus on looking to lt, coarse jerking nystagmus on looking to rt LP clear fluid, cells 210, G +, S — Smear N predominate, "Gram-negative diplococcus" (?) found Urine slight albuminuria 12/8/44 Clouded mentality, irritability, nausea, severe vertigo, tinnitus, nystagmus pronounced, jerking, especially on lateral deviation, limbs flaccid, incoordination in finger-nose test on lt LP clear fluid, cells 500, G +, S — Smear N predominate, no organisms found Patient passed into coma and died

Treatment—Serum 200 ml IV first 4 days Sulphath 37 g 7 days beginning 31/7/44 Onset of meningitis sulphath 4 g, sulphap 9 g, anti meningococcal serum 20 ml IM

Case VIII Malaria, Primary Plague Meningitis

Male one month old admitted 9/7/45, with history of 4 days fever and slight convulsive movements T 104.4° F (40.2° C), irritable fontanelle tense, slight neck rigidity, Kernig's sign equivocal Blood WBC 17,000, film *Plasmodium vivax* gametocytes found (few)

Course—LP attempted many times without success 12/7/45 T 103° F (39.4° C), slight jaundice, neck rigidity +, Kernig's sign — LP few ml turbid yellow fluid, cells 400 G +, S — Smear Gram negative bacillus found (? *Past pestis*) C *Past pestis* isolated 15/7/45 T 99 F (37.2° C) head retraction, Kernig's sign + 19/7/45 T 100° F (37.8° C), pale, wasted, epileptiform convulsions, especially rt face 21/7/45 T 101° F (38.3° C) LP bead of pus at end of needle Smear Gram-negative bacillus found (? *Past pestis*) (LP performed repeatedly from 12/7/45 onwards had only "dry" result) Convulsions generalized, frequent, patient died 22/7/45

Treatment—Sulphap 15 g first 3 days, repeated last 2 days Sulphath 8 125 g, commencing 4th day, for 7 days Serum 50 ml

Summary

Eight cases of plague meningitis are described occurring in a series of 203 cases of plague treated in South China during the years 1943-5

The occurrence of a rare clinical form—primary plague meningitis—is recognized, one case is described and its pathogenesis discussed

We wish to thank Dr Robert Pollitzer, Senior Technical Expert, National Health Administration of China, for his advice and help in the compilation of this paper We would also like to thank our Chinese colleagues, Drs Wu, Ling, and Jao, for their help in treatment, the nursing staff of the hospital for their cheerful co-operation, and Mr C T Lim for performing the laboratory examinations

"SULPHA-COMBINATION"—A NEW CHEMO-THERAPEUTIC PRINCIPLE

BY

A RUNE FRISK, M.D.
GOSTA HAGERMAN, M.D.
STURE HELANDER, M.D.

AND

BERTIL SJOGREN

(From the IVth Medical Service of St Erik's Hospital, the Dermato venereological Clinic of St Goran's Hospital, the 1st Medical Clinic of the Caroline Hospital Stockholm, the Central Laboratories Astra Sodertalje Sweden)

The commonly used sulphonamides—sulphathiazole, sulphadiazine, and sulphamerazine—have on the whole the same effect when employed clinically The two pyrimidine compounds, however, are less toxic than sulphathiazole, and are therefore better tolerated From the therapeutic point of view sulphonamide treatment might be regarded as more or less perfect if it were not attended by the risk of damage to the blood and kidneys Toxic effects on the blood are, however, extremely rare with the above-mentioned drugs Renal complications are more common they may have a toxic or allergic origin, but in most cases are due to a deposition of the sulphonamide compounds, or their acetyl derivatives, in the tubules from supersaturated solutions This risk can be reduced by the introduction of acid-binding media and the maintenance of a high diuresis With these precautions renal complications are rare, but the risk remains, and for this reason inadequate and ineffective doses are often given Thus the importance of reducing concretum formation is evident.

Provided that the sulphonamides do not affect each other's solubility but dissolve independently which is to be expected from the chemical point of view, the risk of concretum formation might be reduced if, for the attainment of a certain blood concentration or effect, not merely one compound but a mixture of several equivalent sulphonamides was employed From the clinical standpoint it cannot make any difference if several compounds are used instead of one when all the drugs are equally effective The risk of concretum formation will, however, be reduced in this case, since each drug in the mixture is present in a considerably lower degree of saturation than when a single compound is employed This new therapeutic principle we have named the "sulpha-combination principle"

In cases where it is desired to increase the dose beyond the normal limits, resulting in higher blood concentration and better therapeutic outcome, the same principle can be applied If in such cases a single compound is used the risk will be increased On the other hand when a mixture of several drugs is employed the risk will be reduced The method has been used in a preliminary form (a mixture of equal parts of sulphathiazole and sulphadiazine) in Sweden for more than three years in the treatment of gonorrhoea (Hagerman 1944, Herlitz, 1944, Werko, 1945) In spite of the very high dosage (12 g a day for four days) remarkably few renal complications occurred (Nilzen, 1946a)

The most important problem is how to avoid formation of renal obstruction with a normal dosage. A mixture of sulphathiazole and sulphadiazine, also suggested by Lehr (1945), is not, however, ideal. The chances of renal complications are admittedly reduced, but they are not eliminated, since some of the excretion products are still supersaturated. If this is to be avoided the two above mentioned compounds must be complemented with a third—for example, sulphamerazine.

In the following account we discuss all the questions connected with "sulpha-combination" and describe experiments showing the practicability of the method. We also give an account of our final mixture, prepared according to this principle—"sulphadital"—which contains the three compounds sulphathiazole, sulphadiazine, and sulphamerazine, equally active in clinical practice. The present article is a condensation of a larger work which has already been published in Swedish (Frisk *et al* 1946).

Solubility

The solubility of sulphathiazole, sulphadiazine, sulphamerazine, and the corresponding acetyl derivatives was determined in solvents saturated with the substances separately and with mixtures of from two up to all six compounds. The solvents used were 1/30 molar potassium sodium phosphate buffer and urine varying in pH. The substances were brought into solution by even mechanical shaking for twenty-four hours at constant temperature—37° C—and with the solutes present in excess. The concentrations were then determined in a photo

FIG 1—Solubility in urine at 37° C over the pH range 5.9–7.9
I=sulphathiazole II=sulphadiazine III=sulphamerazine IV=acetylsulphathiazole V=acetylsulphadiazine VI=acetylsulphamerazine

electric colorimeter according to Bratton and Marshall (1939). The solubility is given in mg of dissolved substance per 100 ml of solvent. The solubility curves are drawn to a logarithmic scale.

For reasons of space we give here only the solubility in urine. Figs 1 and 2 show the solubility at pH 5.9–7.9. From

these it appears that the three sulphonamides, their acetyl derivatives, and all six compounds are, as expected, dissolving independently of one another.*

FIG 2—Solubility in urine at 37° C of different mixtures over the pH range 5.5–8.0

Concrement Formation

We do not propose to review here the comprehensive literature on renal complications during sulphonamide treatment clinically observed or studied in animal experiments. Two main types of injury to the kidney can be distinguished—namely, those of toxic or allergic origin, and those due to the formation of calculi. In the first-mentioned type, which is more uncommon, small areas of focal necrosis are found not only in the tubular cells of the kidneys but also in other organs as well as vascular changes, with fibrinoid degeneration of the media and voluminous intima proliferations.

The changes occurring after calculus formation are localized to the distal part of the kidney, and are characterized by distended tubules filled with masses consisting of protein precipitate, desquamated cells, and crystals of the sulphonamides or their acetyl derivatives. More detailed descriptions of the various anatomical changes have been given by Murphy *et al* (1944), Bergstrand (1946), and others.

In the present investigation the formation of renal calculi has been studied after the administration of sulphathiazole, sulphadiazine, and sulphamerazine. The dose and the blood concentration, as well as the time required to produce obstruction, have been determined for each compound. The composition of our mixture—"sulphadital"—was decided on the basis of these results, and with due respect to the solubility and pharmacological properties of the constituent compounds. This preparation was then subjected to the same investigation in order to ascertain whether the risk of concretum formation had been diminished by the combination.

Rabbits were used for the experiments. They were given a vegetable diet but no water. The urine was acid (pH 4–6). The compounds were administered intraperitoneally morning and evening (eight hours between the doses) every day except Sundays. The animals that did not die spontaneously were killed after about three weeks. Those dying spontaneously usually had concretions, which were the cause of death, but in some cases they died of injuries due to the injections. Twice a week free and total sulphonamide concentrations as well as non-protein nitrogen were determined.

* Further details to be published elsewhere, see also Nord Med 1946 29 639.

As soon as possible after death the kidneys were removed fixed by freezing drying according to Altmann, and then examined under a fluorescent microscope with the histological technique described by Sjostrand (1944) and Helander (1945). With this procedure it is possible to make detailed studies of the preparations without staining. The crystals thus remain *in situ* in the preparations. It is also easy to detect the calculi, as they fluoresce in a characteristic manner (blue fluorescence).

With the method employed it was easy to produce renal obstructions. Their localization and the anatomical picture fully corresponded with previous descriptions. By the polarizing microscope it was also possible to verify the crystalline nature of the concretions. Melting-point determinations in polarized light showed that the sulphathiazole concretions consisted mainly of acetylsulphathiazole, and those of sulphamerazine of the unacetylated compound. As regards sulphadiazine, it was not possible to decide whether the crystals consisted of free or acetylated compound, the melting-points being too close together.

The results have been summarized in Table I. A daily dose of 0.8 g of sulphadiazine per kg body weight during a period

TABLE I—Summary of Results of Experiments on Concretion Formation

Preparation	Daily Dose in g/kg	No of Experiments	Experimental Period in Days (mean)	Percentage of Concretion	Blood Concentration during Experimental Period in mg/100 ml (mean)	
					Free	Total
Sulphadiazine	0.8	5	9	100	18	38
	0.6	5	22	20	7	17
Sulphamerazine	0.6	5	10	100	6	28
	0.4	5	15	0	3	10
Sulphathiazole	0.8	6	16	67	6	11
	0.6	5	18	20	3	8
Sulphadital	2.0	10	12	40	41	63
	1.0	10	18	0	20	30

of nine days was necessary for provoking renal calculi in all the animals. A dose of 0.6 g/kg seldom gave rise to concretions. In the case of sulphamerazine concretions were obtained in all the animals with a dose of 0.6 g/kg in the course of only ten days, whereas a dose of 0.4 g/kg was tolerated without any renal injuries. Sulphathiazole required a daily dose of 0.8 g/kg for sixteen days (the blood concentration was remarkably low, presumably on account of the rapid excretion). In this series, however, only two-thirds of the animals died even though a certain risk attended a dose of 0.6 g/kg. We have therefore considered this dose to be on the whole comparable to the dose of 0.6 g/kg for sulphadiazine and 0.4 g/kg for sulphamerazine. From this it follows that the last-mentioned compound should be present in the mixture in a smaller proportion than the two others.

Finally it was possible with sulphadital to administer considerably higher doses without giving rise to concretions. With a daily dose of 2 g/kg 60% of the animals escaped concretion formation during an experimental period of twelve days, despite the very high blood concentration. If the dose was reduced to 1 g/kg no concretions appeared in any of the animals during an experimental period of eighteen days. The individual components of the mixture with this dosage gave rise to renal calculi in 100% of the cases.

Absorption and Excretion

With the dosage generally employed therapeutically the sulphonamides investigated here are absorbed almost completely, but with increasing oral doses the percentage absorbed becomes progressively less, as with other sulphonamides. The effect of the simultaneous administration of different sulphonamides on the absorption, excretion, and acetylation of the individual compounds was determined in the following way. Various single oral doses of sulphathiazole and sulphamerazine, separately and in a mixture, were administered to each of three healthy persons. The experimental procedure and method of determination earlier employed by Frisk (1943, 1945) were used.

Table II shows the mean blood concentrations in a typical experiment. A simultaneous administration of 2 g of sulphathiazole and 2 g of sulphamerazine gives a concentration that practically equals the sum of the separate values for the two compounds after a dose of 2 g.

TABLE II—Comparison between the Blood Concentrations after Single Oral Doses of Sulphathiazole and Sulphamerazine Separately and in Mixture

Time in Hours	Blood Concentration in mg per 100 ml							
	Found						Calculated

Table III shows the excretion of the drugs in the urine in one of these experiments. The excretion also takes place without the compounds influencing each other. Moreover, the acetylation is unaffected. For technical reasons these experiments were performed with only two drugs.

Composition of the Mixture, its Actions and Uses

Our results thus show that the sulphonamides examined, and their acetyl derivatives, do not affect each other's solubility, that a mixture of several compounds causes concretions to a considerably smaller degree than do the individual drugs at the same blood concentration, and that the compounds in a mixture are absorbed and excreted in the urine independently of each other. Since, as we have also been able to establish, the antibacterial effect of a mixture of several different sulphonamides is not affected but is the sum of the effects of the various compounds, the basis has been laid for the clinical use of the sulpha-combination principle.

A good mixture should contain a number of sulphonamides sufficient to maintain an adequate therapeutic concentration in the blood without risk of concretion formation. The compounds included in it must produce about the same antibacterial effect, be of low toxicity, and possess otherwise favourable pharmacological properties. In consideration of these factors, a mixture of sulphathiazole, sulphadiazine, and sulphamerazine is most suitable. The proportion of the different constituents depends upon their mode of absorption and excretion, their tendency to cause renal injuries, and the solubility of the compounds or their conversion products.

Sulphathiazole should not predominate in the mixture, as it is rapidly excreted and its acetyl derivative is not easily soluble. Sulphamerazine, owing to its slow excretion, gives rise to concretions in a somewhat lower dose than do sulphathiazole and sulphadiazine. The amount of sulphamerazine should therefore be less than that of the two others. The rapid excretion of sulphathiazole and the slow excretion of sulphamerazine can be compensated, however, if the drugs are present

in a certain proportion. We have sought for a mixture that has on the whole, the same pharmacological properties as sulphadiazine, which involves no risk of accumulation, and which it should be possible to administer at intervals of four hours.

The final mixture (sulphadital) was given the following composition: sulphathiazole 37%, sulphadiazine 37%, and sulphamerazine 26%. The normal daily dose in the treatment of pneumonia, for example, is for sulphathiazole 6 g, for sulphadiazine 5-6 g, and for sulphamerazine 4-5 g. A daily dose of 6 g of the above-mentioned mixture thus provides about one third of the otherwise normal daily dose of each constituent.

Figs 3 and 4 show the absorption, excretion, and acetylation of sulphadital after single oral doses of 2 and 4 g (average

FIG 3—Blood concentration after single oral doses of sulphadital: the lower curves after 2 g, the upper curves after 4 g. The curve in each group shows the total amount of sulphadital, the lower curve the free sulphadital, the hatched area indicates the acetylated.

FIG 4—Excretion through the kidneys after single oral doses of sulphadital: the lower curves after 2 g, the upper curves after 4 g. In each group the upper curve shows the total amount of sulphadital, the lower curve that of free sulphadital, the hatched area indicates the amount acetylated.

of three experiments on the same persons). The blood concentration rises rapidly, reaching a maximum after 2-4 hours, whereafter it sinks slowly (Fig 3). The excretion in the urine takes place relatively slowly, and after 48-72 hours is practically concluded (Fig. 4). Of the total dose administered 75-80% has then been recovered, 50-60% in an unaltered form. Thus in the urine about one third of the amount excreted is present as acetyl derivatives.

With the following dosage—2 g at 6 p.m., 2 g at 10 p.m., and thereafter 1 g four-hourly, the first dose being given at 6 a.m. and the last at 10 p.m.—the mean blood concentration (15 cases) of free sulphonamides after 15 hours was 7.8 ± 0.5 mg per 100 ml and that of total sulphonamides 8.5 ± 0.4 mg, the values after 39 hours being 8.0 ± 0.6 and 9.3 ± 0.7 mg, and after 63 hours 8.4 ± 0.8 and 9.1 ± 0.8 mg, respectively. These values agree well with the blood concentrations obtained when the same amounts of sulphadiazine are administered at the same times.

If the dose of sulphadital is increased to almost twice the amount—i.e., 4 g 4 g, and thereafter 1.5 g four-hourly—

the means of the corresponding values (10 cases) are after 15 hours 11.5 and 12.7 mg, after 39 hours 10.8 and 12.0 mg per 100 ml, respectively. There is thus no risk of accumulation even with these high doses. Although the dose has been almost doubled the blood concentration does not increase by more than about 40%, owing to the fact that absorption is less complete when higher doses are given.

Calculation shows that the single sulphonamides at the usual pneumonia doses give such high concentrations of the free compounds and their acetyl derivatives in an acid urine that the compounds are always present in more or less supersaturated solutions. In a neutral urine this also holds for sulphathiazole, its acetyl derivative, and the free pyrimidine compounds, which may be present in concentrations two to three times greater than their solubility. At yet higher pH—e.g., 7.5—the risk is still less, but acetylsulphathiazole and free sulphadiazine may still be supersaturated. Considering these facts, it is surprising that renal complications appear in only a small percentage of the cases.

With the sulpha-combination drugs in the proposed normal dosage the risk of concrement formation is greatly reduced, as the components of the mixture are no longer excreted in the form of supersaturated solutions. This holds good if the reaction of the urine is neutral or approximately so. If, on the other hand, it is more acid the concentrations of two of the excretion products—acetylsulphathiazole and sulphadiazine—may exceed their solubility. For safety's sake a high diuresis should therefore be maintained and the patient should be given acid binding substances. We believe that if these precautionary measures are observed the risk of concrement formation in a normal kidney will be almost eliminated.

Hitherto the sulpha-combination in the form of sulphadital has been used in many hundreds of cases of acute pneumonia with good results and tolerance and without any known case of renal calculi, also with increased doses in many cases of gonorrhoea. Nilzén (1946b) has treated 105 cases of gonorrhoea with increased doses of sulphadital (9 g daily for three days). Although he did not use any acid-binding substances no concrements were observed in any of the cases.

Summary

"Sulpha-combination," a new principle for treatment with sulphonamide drugs, is discussed, and an account is given of sulphadital, a preparation made according to this principle and composed of sulphathiazole, sulphadiazine, and sulphamerazine.

The results are given of a number of experiments illustrating the practicability of the method.

The importance of "sulpha-combination" is twofold. First and foremost, it appears to eliminate the risk of concrement formation at a normal dosage. Secondly, in cases with more resistant bacteria the doses may be considerably increased without greater risk of calculus formation than is possible with a single compound.

Medical practitioners who are asked to give vaccinations and inoculations to intending air passengers are particularly requested to use the "International Certificate of Inoculation and Vaccination" (Form 3150) when recording them. These forms can be obtained by the passenger from the agency from which he receives his ticket and flight information. The use of any other form of certificate is liable to lead to delays and possibly to quarantine in foreign countries where the international certificate is the only certificate officially recognized.

ENDOGENOUS DEPRESSION IN GENERAL PRACTICE

BY

C A H WATTS, MB, BS, DRCOG

In six years of practice before the war I diagnosed only one case of endogenous depression, and that after the patient had committed suicide. After psychiatric experience in the Army I have found the condition comparatively common in general practice. In six months no fewer than 20 cases have come under my care pointing to the prevalence of the complaint. Not many family doctors have the opportunity for postgraduate study of psychiatry and the result must be that a great many cases go undiagnosed. Only a small proportion of the cases, usually the most serious, come before a psychiatrist as the fear of mental-hospital stigma keeps the patient away from specialist help until either the case is certifiable or time itself has effected a cure.

This paper is a preliminary report to draw attention to the endogenous depression which is far more common than is generally realized. The term "endogenous" is used in preference to the term "psychotic" as the latter implies insanity, and few of the patients found in general practice could be certified as insane. Of the 20 cases in this paper only three were considered bad enough for electro-convulsive therapy (E.C.T.). All three stubbornly refused to go to a mental hospital for treatment. Two have recovered without it, but the third is showing no signs of improvement.

One seldom hears of a patient with cancer committing suicide. On the other hand suicidal ideas are common among the depressives. The desire to end things is some measure of the patient's suffering. Depression is probably the most unpleasant illness anyone can contract. With such deadly diseases as cancer or tuberculosis there is always some hope real or built on euphoria, but to the depressed patient, whose condition is far from hopeless, there is no hope and no future.

The mental hospital cases with a general retardation of the psychological and motor systems are fairly easy to diagnose, but for each classical case there are a score of mild depressives who eke out a miserable existence in their homes keeping their troubles to themselves or receiving the only treatment a family doctor can offer, which is often inadequate. Others are

wrongly diagnosed as neurotics, hypochondriacs, and other chronic forms of invalidism. An accurate diagnosis is important, as there is always the danger of suicide. The patient is often reluctant to talk about his feelings and is easily put off by unsympathetic handling. He is only too ready to attribute blame to himself. Thus to be scorned as a neurotic or simply told to "pull himself together" is both cruel and unfair. Frequently his relations have tried these "back-slapping" methods implying that he is either soft or weak-willed. No patient in practice deserves more sympathy. Good rapport, if it can be established between the patient and his doctor, is one of the most valuable weapons with which to treat the disease. Once adequate rapport has been created, such difficult subjects as suicide, the nature of the illness, and the possibility of mental hospital treatment can all be discussed with pleasing candour. The patient may show surprise when such subjects are broached but he is rarely upset by them, because in his heart he has already weighed up such possibilities. "I have thought of suicide, but I should never have admitted it if you had not asked me," is the typical reply to such a question.

Symptoms

The disease is largely symptomatic and it can simulate almost any functional or organic illness. There is an almost infinite variety of types. The following symptoms are the most important, and each will be considered in detail: (a) depression, (b) suicidal ideas, (c) changes in the sleep rhythm, (d) changes in habit and outlook, (e) obsessions and phobias.

Depression

In the type of case one deals with in general practice this is rarely profound, and one cannot always see it written on the patient's face. Close relations usually notice some difference. The patient as a rule complains of one or more somatic symptoms and admits of depression only when questioned directly. The varieties of early symptoms are shown in the accompanying Table.

The patient will usually admit that he is depressed and that his outlook on life has changed. His sense of humour is different from what it was and he rarely laughs. Life has become a burden and every molehill looks like a mountain. Problems and responsibilities he would once have taken in his stride now make him hesitate and hold back. He has lost confidence in himself and his ability. When asked if he or his

Table Showing Varieties of Early Symptoms

Case No.	Sex	Age	Previous Attacks	First Symptom	Sleep	Suicidal Urge	Habit Changes	Work	Length of Illness	Result
142	M	25	None	Patient had malaria	Normal	Present	Asocial	Put off work	3½ months	Recovered
143	F	47		Insomnia	Early waking and bad dreams	None		Carried on in a fish shop	5	"
144*	M	60	Recurr each spring	Depression	Early waking	"		A chronic invalid	2

180	M	47		"	Cannot sleep for cough	Present	None of note	"	10	LSQ

* Case described more fully in text

environment has changed he will usually admit that the change lies in himself. He is a different man from what he used to be. He has difficulty in concentrating and in thinking things out. He has to drive himself to do his work. Even his hobbies have lost all attraction. Actual retardation may be difficult to demonstrate, but the sevens test is sometimes useful. The patient is asked to subtract 7 from 100, and then 7 from 93 and so on, until he has reached the lowest possible digit, which is 2 if his calculations are correct. The usual time for a brain-worker is about 30 seconds. The test can be repeated at intervals, and an improvement in the time is some indication of progress.

To the depressive the future looks very gloomy, if not hopeless, and reassurance is not readily accepted. Delusions, such as poverty or that something dreadful is going to happen either to the patient or to one of his near relations, are not uncommon. The patient is prone to get lost in his thoughts. He may sit for ten minutes before doing a job. One patient, at her worst, could not account for a whole day, but none of her relations had noticed any gross peculiarity during that time. Vertigo or fainting is a common symptom among women.

Suicidal Ideas

This subject must be approached with tact. One does not want to upset the patient or to put ideas into his head. If he admits depression one can inquire if he feels bad enough to wish he was out of it. Most of these patients admit that they have had such wishes. One can then ask if they had had any ideas about suicide. Some will agree, and others who may show surprise will say they have never reached such a pitch of depression.

Sleep Rhythm

Few depressives get off without some upset in their normal sleep habits. The classical story is that they get off to sleep fairly easily, but that the least noise awakens them and their sleep has gone. Others wake up in the early hours and can not get off again. It is during these early hours that they feel worst and suicide is most likely to occur. As the morning wears on they improve and by nightfall feel positively normal, only to waken early the next morning to start the same dismal rhythm again. Some few depressives enjoy good sleep. Others are afflicted with bad dreams and wake exhausted in the morning. Others have difficulty in dropping off to sleep, but such suggests an anxiety state. With some, no two nights are the same. If there is no upset in the sleep rhythm one must seriously question the diagnosis of endogenous depression.

Change in Habit and Outlook

This is often very striking. One patient mentioned that she had always been musical, but since her illness had started she could not bring herself to play the piano. An amateur comedian found himself unable to hold his audience and so gave up his work in the concert team. One patient gave up drinking when depressed. Others go to the opposite extreme.

Case 110—In August, 1945 this patient was admitted to a neuropsychiatric centre agitated and visually hallucinated. His tongue was red and atrophic, and knee jerks were absent. There was a history of heavy drinking to complete the picture of delirium tremens. On intravenous nicotinic acid and aureum he made a rapid recovery, being mentally normal in four days. His family and past history was almost completely negative. He had begun drinking heavily in the February because he could not sleep. Even a heavy dose of brandy could not keep him asleep after 4 a.m. His commanding officer and his wife were closely questioned as to the patient's habits. His wife admitted that since the February he had changed. He had lost all interest in his home and children, never doing the odd jobs about the place to which he was accustomed. He ate and slept badly. The depression appeared to have cleared up with his delirium tremens. Both the patient and his wife affirmed that he was back to normal before he was discharged in October, 1945.

It is well worth while bearing melancholia in mind when a man, previously known to be sober, suddenly starts drinking to excess for no apparent reason.

The social man may find himself shunning society. Others fear to be alone and seek company, but feel out of it when they get there, as they have nothing to say and are so different from what they used to be.

Case 149—This man, aged 38, first came to see me in February, 1946. He complained of stomach ache occurring at intervals, an occasional headache, and a listless feeling. Physical examination failed to reveal any abnormality. His knee jerks were sluggish, but it was felt that his symptoms were those of an anxiety state. During preliminary psychotherapy he admitted a morbid fear of tuberculosis, a disease which had killed his brother. He was reported to the local tuberculosis officer, who had him x-rayed, but no evidence of the disease was found. As he did not report back it was assumed he had been reassured, but towards the end of April his wife communicated with the surgery. She was very worried about him, as "he was a changed man." He was depressed and unhappy, and had dropped all his social activities. He was interviewed again, and it was found that he was very low, feeling that life had lost all its charm for him. Only the thought of his wife and family prevented him from taking his life. He was worried because, while he had earned good money during the war, he had saved nothing and the family ran the risk of poverty. His sleep was poor unless he took sedatives. By the middle of May he was worse, and had a bad suicidal urge. He was taken home one night in a state of depression, and stated that but for the presence of friends he would have finished it. He was persuaded to see a psychiatrist, who suggested he needed hospital treatment at once. The patient consented, but only because he knew if he did not agree he would never get away from the psychiatrist! This man who had been a local comedian and very sociable, became solitary and schizoid. Fortunately, soon after his visit to the psychiatrist he began to improve, and by the middle of July was back at work again.

Case 161—This woman, aged 48, said she had been ill for about a year. She complained of a nasty taste in her mouth and tight feelings round her neck. These symptoms were always most severe in the mornings. She suffered from insomnia and was given to bouts of weeping. She was prone to lose herself for ten minutes or so at a time. She had "nasty thoughts", these usually implied impending death to herself. When her son announced his engagement she had felt happy because she knew he would not have a mother much longer. She had wished she was dead, but when first seen that feeling had passed. She always felt better in company, which she sought, but was embarrassed when people said she was not the jolly soul she used to be.

Obsessions and Phobias

These may indicate an underlying depression. *Case 149* had a phobia about tuberculosis. Other patients reveal absurd consternation about some trivial mole or wart. Early in 1946 one of the local inhabitants hanged himself because of a tapeworm which had worried him for a few months. In the Army the V.D. obsession was particularly common.

Case 27—This man, aged 34, had an obsession about V.D. For over a year, while employed in the Middle East, he had seen every available urogenital surgeon and venereologist. He had twice submitted to cystoscopy. Before returning home he reported once more to yet another camp M.O., who took pity on the patient and threatened him with "You don't want to be sent to a psychiatrist do you?" He ended up at a neuropsychiatric centre, and was given psychotherapy as an obsessional case. He became much worse and made a strong negative transference with his therapist. When seen in March, 1945, there was no obvious cause for any anxiety. He talked too frankly about his sex life, which as Ross (1937) suggested was a pointer towards a psychosis. He had marked feelings of unworthiness, and was always comparing himself unfavourably with others. He was depressed and had suicidal ideas. He slept badly. He was given six E.C.T. treatments and rapidly lost his obsession for V.D. When seen seven months later he was back at work and apparently fully recovered.

Some innocent organ may be blamed for the patient's feelings of ill-health. A man may demand the removal of his testicles, or a woman who has had a prolapse for years suddenly begins to blame it for all her symptoms and is prepared to undergo any operation to have the offending organ removed. Such operations are obviously futile and do not touch the real problem.

On the physical side there is usually no evidence of organic disease. A moderate degree of hypertension is not uncommon. The knee-jerks, which as a rule are brisk in an anxiety state, tend to be sluggish (see *Case 149*). Many depressives are over-laid with a fair degree of anxiety, so that the sign is not of much significance. Depression can of course be coincident with an organic disease, which may make the diagnosis much more difficult.

Case 144—This man, aged 62, was an invalid from chronic emphysema. He had to spend most of his time sitting in a chair,

is the least exertion made him breathless. He was usually cheerful and philosophical about his complaint, but in March, 1946, he became very depressed. He kept to his own room and was solitary. He felt he was finished, and wished he was dead. He had no suicidal urge. His sleep rhythm was changed and he started waking at 3 or 4 a.m. His relations had noticed the change in him. He was given luminal at night and benzedrine in the mornings. In six weeks the depression passed and he resumed his place in the family circle feeling "his old self again."

Diagnosis

Any organic or functional disease can be simulated by the psychotic depression, but the most difficult differentiation is in the field of the psychoneurotic illnesses.

Anxiety State

The differentiation here is most important, because the deeper therapy which is applied to the neuroses is definitely contraindicated in the endogenous depression. Case 27 shows how deep therapy can aggravate the condition.

There are two main aids in the differential diagnosis. An anxiety state can be traced back to its origin in frustration or feelings of guilt. The endogenous depression comes "out of the blue." Secondly, the "feel" of the cases is different. A bereavement will make the normal individual depressed, but his poise should have returned to normal in two weeks. The neurotic may prolong the depressive state over weeks or months. The condition is then known as a reactive depression. It is in fact, a depression brought on by circumstances, and, like all neuroses, is an exaggeration of normal. Furthermore a reactive depression is motivated and serves a useful purpose. The motive lies below the level of consciousness and the purpose may be to get sympathy from the remainder of the family. Bereavement may set in motion an endogenous depression. It might be a factor, but could not be the sole cause of the illness. Much more frequently this disease comes "out of the blue." Wringing her hands, the patient exclaims "And I should be so happy. I have such a nice home and husband and I am so proud of my family." The illness is not engendered by circumstances and is not motivated like an anxiety state.

The second important point in the diagnosis is the "feel" of the case. It is quite different from any other illness, and the ability to feel out cases comes from the experience of handling them. The typical depressive oozes with depression—so much so that the physician himself feels depressed. This does not often happen in the mild cases described in this paper. The kind of rapport one establishes helps in the differentiation. The neurotic who is going to respond shows an intellectual interest in his treatment. The depressive allows talk to flow over him and only appears to be interested in going over his feelings. He is never tired of telling his story over and over again. Thus with the depressive the psychotherapy is more stereotyped and easier than with the neurotic. It consists of repeated encouragement and while the repetition may not appear to convince the patient it does not bore him. In the anxiety state there may be a hidden fear of mental illness. The patient would be very upset if this were suggested by the therapist. The depressive accepts, without resentment, the suggestion that his illness is mental although he will dig his heels in hard at the mention of a mental hospital. In his heart he knows the way he is heading. He is grateful for the diagnosis perhaps because he is glad to find someone who understands and can sympathize. He is so often misunderstood.

Prognosis

The one bright spot in this gloomy illness is that the prognosis is comparatively good especially in cases of involutional melancholia. The length of the illness varies from a matter of a few weeks to months or even years. Henderson and Gillespie (1944) suggest that when relatives press for an opinion it is best to state that the attack may last for a period of 3 to 6 months. Many cases are well in much less time, but others run a longer course—maybe of years. With ECT dramatic recovery is likely to occur in anything from 50 to 70% of cases of involutional states according to Sargant and Slater (1944). Henderson and Dalrymple (1943) in a review of ECT suggest 46% recovery in other types of depression. High-dosage insulin sometimes works where ECT has failed especially in the

depressive case with schizoid characteristics. The recovery figures do not appear startling when compared with the results in the appendicectomy operation, but they are very much better than those of older methods of treatment, and in successful cases the patient is relieved of weeks or months of suffering. With patients it is wise to take a very optimistic view of treatment, but one should give the relatives a more accurate statement as to the prognosis.

Treatment

The first step in the treatment of these cases is to establish a firm rapport. The illness may be a long one, and such a rapport may well carry the patient through the bad patches when everything else seems hopeless. So far as general practice goes, the treatment is threefold—psychotherapeutic, symptomatic, and occupational.

Psychotherapy

In his book *The Common Neuroses* Ross (1937) devotes an excellent chapter to the treatment of the mild depressive. The therapy consists largely of reassurance, and the same ground may be gone over again and again without the patient becoming bored by repetition. He should be told that his symptoms are due to an illness which is not uncommon, and which is well understood by the therapist. "I am not really ill" is a common apology offered by a patient, and it comes as a relief to know that his feelings are the expression of an illness and not due to his own peculiarity and failings. Surprise and satisfaction are often expressed when the therapist, in his pattern, is able to describe some of the patient's symptoms more clearly than the patient himself. The patient realizes that here at least is someone who understands, someone to whom he can talk without being laughed at or told to "pull himself together." The only consolation is that, if he can hang on, the illness will pass over. He must be reassured that, in spite of any feelings to the contrary, the illness is self-limiting. One cannot remove a delusion by argument, but this analogy sometimes gets home. The patient is told that his "dashboard instruments" are recording falsely, and he needs to be guided by those of his doctor and his relations until accuracy is restored. He must be told to measure his progress, not by days, but by weeks or months. Even when he is climbing out of a depression he must be warned against setbacks, which frequently occur. These may be accompanied by a strong suicidal urge. Nothing is more disappointing than to lose a patient who seems to be well on the road to recovery.

Symptomatic Treatment

Every effort should be made to promote sleep. In some cases 1-3 gr (65-195 mg) of phenobarbitone is adequate but usually 7½ gr (0.5 g) of medinal is more effective. The latter is taken dissolved in water and flavoured with sugar and fruit juice. Benzedrine sulphate is sometimes useful in dispelling the early morning depression, and creating "pep" and energy in the patient. One or two 5 mg tablets are usually given on waking. Another may be necessary by noon. To avoid creating insomnia at night none are administered later. Aspirin compounds may be given to relieve headaches and alkaline powders to allay dyspeptic symptoms. Stilboestrol is useful to abate menopausal symptoms, but does not in itself relieve the depression. There is no need to withhold any drug which promises to relieve discomfort merely because the pain is psychogenic but it is more important to promote reassurance and understanding than to give any form of medicine.

Occupational Therapy

This is most important. The patient is often quite unable to do any responsible work but to make him idle by merely putting him off work is to invite trouble. Time drags horribly with a depressive and anything which helps him to while away an hour is useful. He should be encouraged to do things with his hands, and to be sociable with his friends. He should be discouraged from lying idly on his bed or going for walks by himself with only his own wretched thoughts for company. Perhaps more important than the negative aspect of while away his time is the positive side of achievement. The patient feels useless and impotent and it is often an encouraging surprise to him to find he can do even small jobs.

Specialist Treatment

E.C.T., insulin shock, and in certain cases leucotomy require specialist attention. Few forms of treatment in the whole of medicine are more dramatic or more gratifying than E.C.T. in the depressive, especially the involuntal type, and here comes the rub. Very few cases found in general practice are certifiable. The patient does not resent the mental implication of the diagnosis, but he resents strongly any idea of being sent to a mental hospital for treatment. The bait of going in as a voluntary patient, of having a special ward, is quite ineffective. If the patient is suicidal the position is most embarrassing for the doctor. To send a patient in against his will would break a useful rapport. It is maintained by some psychiatrists that E.C.T. given to a resistant patient is less effective than to one who voluntarily submits.

The G.P. is looking after a large community. If every depressive were certified and sent to a mental hospital for treatment not only would his practice diminish but he would vitiate his own work. Few neurotics and depressives would have courage to confide in a man who was liable to lock them up. In any case, in America E.C.T. is given to out-patients, and the majority of mild depressives could well be treated in that way.

It is high time that every general hospital had a neuro-psychiatric wing where neurotics, depressives, and amenable psychotics could be treated without the stigma of the mental hospital to add to their misery. Such a cover has already been given to patients suffering from venereal disease but it is denied depressives, who are more deserving of such help. If all able cases were treated as out-patients that would save valuable hospital beds. Calling a lunatic asylum a mental hospital is a theoretical improvement, but it has not in any way allayed the public dread of such an institution. Furthermore any "nerve hospital," no matter what euphemism labels it, is doomed to similar unpopularity. Only by incorporating the centre into a big hospital will the stigma be avoided.

During the war psychiatry has made great strides, especially in the Armed Forces. Psychiatric facilities are urgently needed by the civilian population. It is estimated that one-third of all the cases seen in general practice are functional. Psychiatric specialist facilities are meagre in the extreme. Under the present system the vast majority of mild depressives, who are far from "insane," will have to get along as best they can with the inadequate treatment which the G.P. can offer. There will be a proportionate number of suicides, which with a better system would be avoided.

Summary

Attention is drawn to the prevalence of the endogenous depression in general practice. It is a diagnosis which is often missed.

The main symptoms, the diagnosis, and the domiciliary treatment of the condition are outlined.

The difficulty of procuring special treatment is pointed out.

An appeal is made for better psychiatric facilities in general hospitals, so that amenable patients can avoid the stigma of mental hospital treatment.

SIR JOHN CONYBEARE'S *Textbook of Medicine* by various authors first appeared in January, 1929, and by April 1945 had gone into seven editions and four reprintings. Now it has reached an eighth edition (E. and S. Livingstone, 30s.) and the editor's skill in managing his team is no less evident than before. Most of the sections have needed only minor touching up. F. E. Lipscomb has largely rewritten the articles on malaria, blackwater fever, bacillary dysentery, and typhus and that on effects of heat has been rewritten and transferred to the section on tropical diseases. In the section on the endocrine system there is a new article on the menopause, and many changes have been made in those on thyrotoxicosis and diseases of the pituitary gland. Now that penicillin is more and more available and there is a large literature about its use, the editor has added a section on the subject. There is also an appendix on aviation medicine by R. H. Winfield. This textbook has won a firm place in the esteem of students and practitioners, and the new edition will maintain its well-deserved popularity.

SO-CALLED TRIPLE-SYMPATOM COMPLEX OF BEHCET

BY

E. W. PROSSER THOMAS, M.D.

In 1937 H. Behcet described what he believed to be a hitherto unrecognized morbid entity in which grave eye disease occurs in association with peculiar ulcers of the mouth and external genitals. Later he published other articles (Behcet, 1938, 1939, 1940). The clinical picture naturally is dominated by the eye lesions, which range from conjunctivitis and corneal ulceration to hypopyon uveitis, and may lead to total blindness. The eye involvement may precede, coincide with, or follow the oral and genital manifestations. Both eyes may be affected simultaneously, but more usually only one eye is involved for a while, after a variable interval the other eye shows similar changes. The ulcers of the mouth and genitals are small and discrete, either aphtha-like or nodular and necrotic, resembling perianthitis mucosa necrotica recurrens (Sutton). Other skin lesions may also occur, such as erythema nodosum or an acneiform eruption. The disease, which appears to affect men twice as often as women and to occur predominantly in the third decade of life, is essentially a relapsing one over a period of years, the symptoms at the three main sites recurring simultaneously or successively. Behcet believed the syndrome to be due to a filtrable virus.

A similar combination of symptoms had been reported earlier—for instance, by Whitwell (1934) and Nishimura (1935). Whitwell concluded that there is a relatively unexplored syndrome of ulcers in the mouth accompanied by "embolic lesions elsewhere," the syndrome may be partial—that is, mouth lesions alone—but at any time the skin and/or the vulva may be involved, eye lesions may also occur, as in one of the cases he cited. Nishimura's case was one of acute ulcer of the vulva with aphthoid changes of the oral mucosa and acute iritis.

Since Behcet's articles a number of other cases of the same complex have been reported (Weekers and Reginster, 1939, Bechgaard, 1940, Cavara, 1940, Franceschetti and Valerio, 1940, Mach *et al.* 1941 and Ephraim, 1944). The last-named author questioned whether *ulcus neuroticum oris et vulvae* (Loblewitz) *perianthitis mucosa necrotica recurrens* (Sutton), and aphthosis (Neumann) do not all belong to the same group. A case recorded by T. Jensen (1941) may be quoted as an example of the syndrome.

The patient was a man aged 22. The disorder began with aphthoid ulcerations of the mouth at the age of 9, the ulcerations healed spontaneously in a few weeks, then recurred. Ocular symptoms appeared at 12, lasted four or five days at first and then about three weeks, and recurred at intervals of one month. Vision decreased after each attack. Iritis, iritis and choroiditis total atrophy of the left and partial atrophy of the right optic nerve, and hypopyon were successively diagnosed. Six years later small painful ulcerations developed from time to time on the scrotum and penis. The patient gave a positive response to intra dermal tests with tuberculin, Frei antigen, and dmeclos vaccine. Non specific reaction was therefore suspected and confirmed by positive response to 0.1 ml. of a physiological salt solution. Superficial puncture of previously sterilized skin caused the appearance of a pustule the size of a pinhead and surrounded by a red somewhat infiltrated zone having a diameter of 5 mm. The pustule disappeared in four to five days, leaving some epidermal scarring. Behcet inclusion bodies were not found in the secretion of the regular ulcerations.

A case recorded by Berlin (1944) is of especial interest because, in addition to the classical eye, mouth, and genital lesions, the central nervous system was involved. Berlin's patient whose eye disease began three and a half years after the oral and genital signs, eventually developed headache, giddiness, and fits, which culminated in coma and death. At necropsy small multiple foci of inflammation and softening were found in the brain.

The subject has been fully reviewed recently by Curth (1946) and Katzenellenbogen (1946). Curth describes the first American case of the disease. The patient was a young man with typical recurrent hypopyon which led to the enucleation

of one eye and to blindness of the other, with recurrent genital ulceration and oral aphthae. Other symptoms were attacks of arthritis of the ankles and fibrositis of the back. The patient also suffered from facial acne, recurrent boils and multiple abscesses in the axillae. There was no response to a number of different treatments, including systemic penicillin and sulphoamides. Bacteriological and other studies gave no clue to the aetiopathogenesis.

Katzellenbogen reports three cases in male Arabs. There were recurrent aphthous ulcers in the oral mucosa and in the skin of the root of the penis and scrotum which left scars on healing. The ulcers were associated with eye disease of the character of hypopyon iritis and with haemorrhages in the retina and vitreum. These haemorrhages, which have not been stressed by other authors contributed most to the loss of sight in two of the cases. Other lesions noted were nodules resembling erythema nodosum on the extremities and an acneiform eruption on the face, extremities, and back. Relapsing epididymitis was found in two of the cases. All cases had a peculiar sensitivity of the skin. Puncture was at all times followed by pustule formation, and any injection, of whatever material, produced focal erythema and swelling. In his cases Katzellenbogen found no evidence to support Behcet's belief in a virus causation, and failed to discover any grounds for suspecting tuberculosis. He thought, however, that the disease had qualities reminiscent of those of herpes.

The following appears to be the first case of Behcet's syndrome as such to be reported from this country.

Case Report

A married man aged 29 came under observation at St Mary's Hospital in June, 1940 on account of a relapsing iritis in the right eye. He was employed in a munitions factory as an inspector of shells. Previously he had worked for five years as a paint sprayer. His father, mother, one sister, and one brother were alive and well. One sister had died of pulmonary tuberculosis. He had had scarlet fever at the age of 11. Before the onset of his eye disease his general health had been fair, but for eight years—that is from the age of 21—he had suffered from ulcers of the tongue, roof of the mouth, and inside of the cheeks. These ulcers recurred irregularly, each lesion taking three or four days to mature and about the same time to subside. They were generally painful. Some were small and superficial resembling simple aphthae but others formed more solid nodules which broke down centrally and left scars (cf. *perianteritis mucosa necrotica recurrens*, Sutton).

In September, a few months after the onset of iritis he developed a right femoral thrombophlebitis. Except for a positive Mantoux test, full investigation in hospital proved as negative at this time as it did subsequently. Focal sepsis was suspected in the tonsils, and tonsillectomy was performed in October. The disease however progressed, and in December thrombosis of the inferior vena cava occurred. Meanwhile the condition of the right eye had been steadily deteriorating. By March, 1941, vision was practically nil and there was extensive damage involving the whole uvea. The left eye also was slightly threatened. A search for a common focus of infection for the thromboses and the iritis failed as did that for a tuberculous focus in the chest or elsewhere. Naturally it was regarded as suspicious that his sister had died of pulmonary tuberculosis.

By July the thrombosis of the inferior vena cava was subsiding though the patient still had slight swelling of the legs after exercise, which was controlled with elastic stockings. He had been treated with prolonged rest, which when interrupted brought on exacerbations of the iritis in the right eye. The left eye had been flaring up periodically.

In August he was again admitted to hospital this time with nausea, constant insomnia and severe temporal headache. The eye lenses were equivocal and a cerebral neoplasm possibly with meningeal involvement was suspected. Lumbar puncture showed a raised pressure (250 mm) with a clear fluid. The cell content was normal, the chemical and bacteriological examination negative. The colloidal gold test was negative as was the Wassermann, which had been done on the blood on a number of occasions previously. Radiography showed no evidence of an intracranial space filling lesion. An encephalogram gave no positive result. In view of his past occupation as a paint sprayer a lead encephalopathy was suspected but there was no evidence of skeletal lead deposition and the lead content of the urine was 0.08 part per million (normal, 0.04-0.12). No suppurative erythrocytes were seen in the blood. Apart from a haemoglobin of 76%, the blood count was within normal limits. Blood culture was sterile. General physical examination apart from revealed no definite abnormal signs in the central nervous system, heart or abdomen. Large veins were now present below

Poupart's ligaments and across the abdomen, carrying blood upwards, presumably a relic of the bilateral femoral thrombosis. The posterior tibial arteries were present and palpable.

Meanwhile, vision in the left eye had become suddenly worse and the headaches had increased in severity. An extensive white exudate from the choroid was seen, suggestive of choroiditis rather than papilloedema. After another month's rest, however, the headache had lessened and vision in the left eye had improved somewhat. The superior quadrants had cleared a little, but details were still not visible. He was again discharged to the out-patient department without any aetiological diagnosis having been made.

Shortly afterwards a new set of symptoms made their appearance—namely, various skin lesions, and ulcers on the scrotum and penis. The skin lesions were of three types: (a) Small, solid, slightly tender papules on different parts of the body, particularly the forehead, cheeks and legs. They were of normal skin colour or sometimes a little dusky, and came and went within ten days or so without ever breaking down. (b) Small patches of erythema—e.g., on the chest and arms. These were thought to be due to thrombosis of a surface vein. (c) Larger, more tender nodules of erythema nodosum type particularly on the thighs, giving an appearance of inflammation. One of these lesions on the leg was excised for section and was reported as showing an acute inflammation of a vein with thrombosis, many polymorphs were seen in the thrombus and around the vessel, the inflammatory process spreading a little distance into the surrounding tissue. No organisms were seen. Aerobic and anaerobic cultures were negative. The ulcers on the scrotum and penis recurred every two weeks or so, sometimes more than one appearing at a time. They began as small, solid, tender nodules which broke down to form a sharply punched-out ulcer with a yellowish necrotic base. They invariably left scars.

In December the patient was readmitted to hospital with intense pain in the right eye and side of the head. Excision of the eye was then performed. The headaches, however, continued, now mainly left temporal and vision failed completely in the remaining eye. He was again admitted to hospital in May, 1942 and fully investigated. His case was now, *faute de mieux* labelled "thrombophlebitis migrans". The bleeding time, clotting time, and platelets were normal. The blood count was Hb 70%, white cells, 14,100 (polymorphs 73%, lymphocytes 23%, monocytes 1%, eosinophils 2%, basophils 1%). The electrocardiogram was normal. The Mantoux reaction (1/10 000) was weakly positive. As vision had failed completely and the headache and distressing pain persisted in the left orbital region, enucleation of the left eye was carried out in June.

After-history—The patient attended the out-patient department periodically for the next two years and was treated symptomatically. His case was reported on as follows:

"January 1943. Since discharge from hospital gets aching pain in left hip radiating to calf. Still has red nodules, especially on thighs. No further ulcers in scrotum or mouth. Spleen and liver not palpable. BP 118/75. Dilated veins on abdomen, especially on left. Both posterior tibials and popliteals palpable. Left calf tender. Left ankle jerk brisker than right. Hyperaesthesia to touch round left ankle? early neuritis. May, 1944. Now has pain across forehead, especially on coughing. Giddy turns and fainting attacks no fits. Legs getting weak. No sphincter disturbance. No abnormal physical signs in central nervous system. Some occipital fibrositis. Caput medusae well marked."

Eventually the patient found the journey to London too difficult because of his blindness and air raids, and ceased attendance. It has not been possible to ascertain his subsequent history.

Ophthalmic Summary

I have to thank Mr Frank Juler for the following note:

"The ocular condition manifested itself first in June, 1940, in the form of subacute recurring iritis of the right eye with hypopyon. After some four attacks at monthly intervals the visual acuity was reduced to 6/24 but soon after, in December 1940 there was a fairly sudden loss of vision, with a central scotoma due to a lesion probably in the choroid. Further congestive attacks occurred in the right eye, and perception of light in this eye was lost by October 1941. In this month glaucoma ensued, and the right eye was removed on account of pain.

In the meantime the left eye was also attacked by subacute iritis in October 1940 but in February, 1941, fine vitreous haze and patches of choroidal change in the periphery were noted with vision still 6/6. In June, 1941 this eye suddenly became defective, and vision fell to finger-counting at 15 metres. Much vitreous opacity was present and severe headache became a marked feature. In two months the eye had cleared to 6/18, and a scotoma was present owing to a large white area in the fundus near the optic disk. In September 1941, the left eye became suddenly worse with severe congestion and headache, and by October vision was reduced to perception of light. A recurrence of iritis with hyphaemia did not improve matters, and in May, 1942, with severe pain in the head

and congestion of the eyeball, perception of light was lost. Recurring glaucoma with pain led to excision in June, 1942.

Histological examination of the excised eyes threw little light upon the aetiology. There was complete detachment of the retina, with gross intraocular haemorrhage, chiefly subretinal. Marked patchy thickenings of the ciliary body and choroid were evident, showing reactionary changes, but there was no certain evidence that vascular thrombosis was the initial factor.

Medical Memoranda

Intravenous Anaesthesia and Circulation Time

In all the better-known techniques for the induction of anaesthesia by the intravenous route a safety pause of 20 to 60 seconds is recommended. It is generally stated that this interval must be allowed in order to observe the effect of the drug on the patient. It seems to me more likely that its function is to permit the blood stream to transfer the drug from the site of injection to the brain. The following investigation was carried out in order to obtain more accurate information on the matter.

Investigation

Thirty-two patients were given, by intravenous injection at the elbow, 3 ml each of a 10% solution of hexobarbitone or of a 5% solution of pentothal (thiopentone B.P.). In all cases this was enough to make the patient go to sleep. The duration of the period of injection (A) and the interval from beginning the administration until the patient ceased speaking (B) were measured. It was assumed that half-way through the injection period a sleeping dose for an average patient had been given. The mean interval between the administration of this amount of drug and its action was thus obtained (Table I). It was

TABLE I—Mean Interval between Administration and Action of Drugs

Drug	No of Cases Studied	Mean Injection Time (A)	Mean Interval until Onset of Sleep (B)	B—A
Hexobarbitone	12	7.5 secs	19.2 secs	15.5 secs
Pentothal	20	8.0	20.0 "	16.0

identical for hexobarbitone and pentothal. Further, it approximated to the arm-tongue, arm-carotid sinus, and arm-arm circulation times determined by the ordinary methods (Table II).

TABLE II—Circulation Time determined by Ordinary Methods

Author	Circuit Studied	Circulation Time	Agent Used
Gargill (1933)	Arm-tongue	15.9 secs	Sodium dehydrocholate
Fishberg <i>et al</i> (1933)	Jugular vein-tongue	13.2	Saccharin
Blumgart and Weiss (1927c)	Arm-tongue	12.0	Radioactive material
Blumgart and Weiss (1927b)	Arm-arm	18.0	Sodium cyanide
Robb and Weiss (1933)	Arm-carotid sinus	15.6	

The corresponding interval was determined in four cases for drugs injected into the internal saphenous vein at the ankle. It was found to be 35, 45, 45, and 55 seconds. Presumably the greater delay was due to the longer course which the drug traversed on its way to the heart.

The interval which occurs between the injection of an effective dose of an intravenous anaesthetic and the appearance of

its action is therefore entirely traceable to the time required for its transfer from the site of injection to the brain. In normal individuals a matter of 15 seconds will suffice for drugs injected at the elbow or into the external jugular vein. As much as 60 seconds may be necessary when the veins of the foot and ankle are used. The normal circulation time is seriously prolonged in patients suffering from myocardial failure (Table III). Therefore, in the presence of any form

TABLE III—Circulation Time in Heart Disease

Author	Circuit Studied	Circulation Time	Pathological Condition
Blumgart and Weiss (1927c)	Arm-arm	22-51 secs	Arteriosclerosis and myocardial degeneration
Blumgart and Weiss (1927b)	"	30-55 "	Auricular fibrillation
Gargill (1933)	Arm-tongue	15-71 "	Rheumatic heart disease
		17-48 "	Syphilitic aortitis
		20-52	Congestive heart failure

of serious cardiac disease great caution must be observed in the giving of intravenous anaesthetics. Methods which employ fixed rates of injection offer no protection against accident in such cases. The only safe procedure is to inject an initial small sleeping dose and observe what time elapses before its effects are apparent. A similar interval must be allowed for the appearance of the action of subsequent doses.

Landry's Paralysis

The following case of Landry's paralysis is thought to be worth recording because of the rarity of the condition.

CASE HISTORY

A man aged 26 was admitted to hospital complaining of weakness of the arms and legs. He had been demobilized from the Navy six months previously and had been quite well until ten days before admission, when he had had a short bout of vomiting and diarrhoea. Three days before admission he developed "pins and needles" in his fingers, and his hands felt weak. Next day he could not move his fingers at all and his feet alternately burned and felt cold and numb. By the third day he was unable to stand because of weakness of the legs.

On admission on the fourth day, he had a complete flaccid paralysis of the muscles of the hands and forearms and of the triceps and deltoids. All the other muscles of the limbs and trunk showed extreme weakness bordering on paralysis. All reflexes except the cremasterics were absent. There was also aphonia and retention of urine. The bowels had not been opened for two days. The muscles of the head and neck were normal. There was slight blunting of sensation on the hands and feet, otherwise sensation was unaffected. The temperature was 99.2° F (37.3° C) on admission, but never exceeded 98.4° F (36.9° C) during the remainder of his stay in hospital. There were no other symptoms or abnormal findings. Examination of the cerebrospinal fluid showed pressure and appearance normal, total protein 0.140%, other constituents normal. W R and Langes test negative. The blood contained 14,000 white cells per cmm (85% polymorphs), and the W R was negative. X-ray examination of skull and cervical spine revealed nothing abnormal.

On the fifth day the patient regained control of his bladder, and the bowels functioned normally after the administration of an enema. The paralysis continued to extend, however, and reached its height on the seventh day. At this stage there was aphonia, slight dysphagia, and flaccid paralysis of the whole body except the diaphragm and the muscles of head and neck. The cremasteric was the only reflex which could be demonstrated.

On the same day the first signs of recovery were noticed—his ability to make slight movements of the fingers. By the ninth day the fingers moved well and the arms could be flexed. By the twelfth day the voice was noticeably stronger, one leg and both arms moved well and there was at least a little power in all the affected muscles. The knee jerks and plantar responses returned on the eighteenth day and all the other reflexes during the following week. The patient was discharged, completely recovered, five weeks from the onset of paralysis.

I am indebted to Dr W H James, medical superintendent of the Beverley Emergency Hospital for permission to publish this case.

Reviews

DISEASES OF THE ADRENALS

Diseases of the Adrenals By Louis J. Soffer, M.D. (Pp. 304 illustrated with 42 engravings and two coloured plates 28s.) London: Henry Kimpton 1946

Although diseases of the adrenal glands are uncommon they are of profound interest because of their far reaching effects on the mental and physical well being of the patient. Dr Soffer is well qualified to describe them, for he has had considerable experience of clinical practice and experimental research in this field. His book begins with an account of the anatomy and embryology of the adrenals and a useful summary of the chemical and other special investigations used in the diagnosis of adrenal disease, an account is then given of the physiology of the adrenals. The number of steroid hormones isolated from adrenal cortical extract at present totals 25, and it is expected that more fractions will be isolated in the future, there is presumably some form of mutual balance or synergy between them. This is illustrated by the fact that the whole extract will not produce hypertension, and desoxycorticosterone will not produce hypertension if the adrenals are intact but will do so in patients with adrenal insufficiency.

Cortical extracts have been used in various forms of shock during the war but on the whole the results have been disappointing. Addison's disease is described in detail, and Dr Soffer shows that with modern measures a third of his patients are alive four to seven years after the institution of treatment. There follows a fascinating study of the adrenogenital syndrome. The active male sexual life of many female pseudo-hermaphrodites and the psychical changes in Cushing's syndrome are remarkable biological phenomena not only are they of importance for psychosexual theories, but they are of great practical concern, for the incidence of pseudo hermaphroditism is approximately 1 in 1000 people. Finally there is an account of the tumours of the adrenal medulla. Dr Soffer handles his subject and its copious literature with complete control, his style is clear and readable, and he has done full justice to the subject in fewer than 300 pages. His monograph is well printed and illustrated, it is greatly to be commended.

GROUNDWORK OF PHYSICAL TRAINING

Principles of Anatomy and Physiology for Physical Training Instructors in the Royal Air Force (Pp. 180 158 figures 7s. 6d.) London: H.M. Stationery Office 1946

This small and attractive book, authorized by the Air Council and introduced by a foreword written by the late Director-General Sir Harold Whittingham, has many things to commend it not only to physical training instructors, for whom it is written but to many general practitioners. 'P.T.I.s' cannot fail to have their enthusiasm and interest captured by the simplicity and clarity of presentation by the attractive illustrations and diagrams and the comfortable style of simple English in which it is written. 'G.P.s' who are not too proud but are ready to admit rustiness in their anatomy and physiology will find this book a most attractive means of refreshing their knowledge with a minimum of trouble. But one word of warning: the example of a day's diet on page 105 must have been the work either of someone living in the past or with foreknowledge of the early lifting of food rationing. Here it is stated that 'The calorie requirements of a man doing light manual work are shown below expressed as a specimen diet for twenty-four hours. Do those who come under R.A.F. physical training instruction really have porridge, bacon (2 oz.), egg, sugar, marmalade, butter, and white bread for breakfast? Is this a subtle way of leading us into State secrets and are we entitled to drink their health in the pint of milk that appears later in the diet?' But apart from this at the moment obviously impractical example the physiological section is extremely well presented.

The chapter on medical rehabilitation in the R.A.F. makes fascinating reading. Every consultant, practitioner, physiotherapist as well as P.T. instructor who studies this book will be a gainer and will certainly improve his understanding of the science of rehabilitation.

INDUSTRIAL TOXICOLOGY

Industrial Toxicology By Alice Hamilton, M.D., and Rutherford T. Johnstone, M.D. Edited by Henry A. Christian, M.D., Sc.D. (Pp. 125 15s.) New York and London: Oxford University Press 1946

This book is a reprint of a section of the Oxford Loose Leaf Medicine and has the same page numbers as in that work. Industrial medicine is an artificial grouping of different sections of medicine which have an application in industry. These include physiology, psychology, heating, ventilation, statistics, skin diseases, accident surgery, ophthalmic medicine and surgery, industrial pulmonary disease and industrial toxicology. These subjects are so diverse that a man may cover them in a form of general practice but no individual can possibly be an expert in every branch. The subject of industrial toxicology, the knowledge of injurious actions of substances used in industry, has always been important, it is perhaps the most important branch of industrial medicine so much so that the two have often been regarded as synonymous. Its importance has rapidly increased during recent years with the flood of new and complex chemicals which find their way into industry for diverse purposes. One cannot therefore but welcome a new book on toxicology from the United States, even though the principal criticism of the book is that, though published in 1945, it has not appeared in this country until August 1946 and it conspicuously does not refer to much of the newest work on the subject such as manganese pneumonia, the latest reported cases of beryllium poisoning, and tri-ortho-cresyl phosphate. Nevertheless it is a full book, well written and well documented.

Many doctors are now faced with the problems of the diagnosis and treatment of injuries and diseases developing in workers by reason of conditions associated with their work. This applies not only to the industrial medical officer and general practitioner but to every physician who may be consulted by a worker. This book should therefore appeal to a very wide field and we can with confidence commend it to all of them.

CATALAN CULTURE

The Spirit of Catalonia By J. Trueta (Pp. 198 8s. 6d.) London: Oxford University Press 1946

The rise and fall of the Catalan culture on the eastern seaboard of the Iberian Peninsula and in the south of France is less well known in England than its peculiar interest merits. From the tolerant, humane, inquiring spirit of thirteenth-century Catalonians was created the first democratic government in the world: all society was represented—ecclesiastics, noblemen, villagers—and no law could be passed without the approval of their representatives: a state of affairs epitomized by Lullius writing at about that time: "Men are serfs of other men but their ownership my Lord is not essential but accidental."

This concise and scholarly book by the eminent Catalan surgeon is as crowded as an illuminated missal with portraits of Catalonia's famous men—Lullius, Arnau de Vilanova, Sibiude, Vives, Servetus (the first to suggest the blood's circulation)—and though the style is marred at times by a flatness inappropriate to the exposition of a people's spirit the matter is well worth the general reader's attention. There are still lessons to be learnt from Arnau de Vilanova, author of many medical treatises accusing the teachers 'of losing themselves in universals and ignoring particulars, as well as of their unfounded therapeutical empiricism which lost itself in particulars and ignored general principles', and from Sibiude's neatly incised bridge between scholasticism and humanism.

Man is the limited reproduction of the Creator and thus a scientific knowledge of man may bring us by successive steps to the knowledge of God.

The history of a people such as this, blessed at its birth with the poetry of Provence tempered by conflict with the Moors, rising to great maritime power and summits of philosophical thought, only to sink back into oblivion, poses, as we have suggested a problem of particular interest to us: what is the nature of that cultural force which suddenly liberated, waxed so imperiously and as inexorably declines? The accretions of the course are well described by Dr Trueta—the policy of Ferdinand (Machiavelli's *The Prince*), the Inquisition, the alien military coups. The essence remains as inscrutable as the curve of an individual life.

PHARMACEUTICAL ASPECTS OF PENICILLIN

Penicillin Its Properties Uses and Preparations (Pp 199, illustrated 10s 6d) London The Pharmaceutical Press 1946

Penicillin Its Properties Uses and Preparations is published by direction of the Council of the Pharmaceutical Society of Great Britain, and its authorship is undisclosed. Said to have been inspired originally by a stream of inquiries coming to the editor of the *Pharmaceutical Journal*, it has been expanded into a scholarly treatise which will be found a useful work of reference. It concludes with a bibliography of 331 items. This book has evidently been written chiefly for the benefit of the pharmacist, and deals exhaustively with the aspects that concern him most. There is a whole chapter devoted to the question of stability, and the account of penicillin preparations is one of the most complete yet to appear, many alternative formulae being given. The account of clinical uses, though occupying only a single chapter of 34 pages, is adequate as an outline of the scope of penicillin treatment and of the general lines which it should follow. In this chapter it is repeatedly suggested that a dose of 200 000 units or more given twice daily is adequate for many purposes. This is a wasteful if convenient system, and evidence that its effect equals that of much smaller doses given frequently is not yet forthcoming.

There is a somewhat resentful reference in the preface to the suggestion made in the earliest days of treatment with penicillin that its dispensing should be undertaken "by bacteriologists rather than by those trained in such work." No one would wish to maintain this attitude to day, but let it not be forgotten that a good aseptic technique is still necessary. It is admitted on page 115 that some pharmacies are structurally unsuitable for aseptic dispensing. There is a tendency in other directions to reverse the policy of 1943, it is emphasized that some preparations need not be sterile, that economy is no longer necessary, and that bacteriological diagnosis is superfluous. These encouragements to lavish use may be justified by the present supply position and such use there will certainly be whether encouraged in print or not. We nevertheless find it rather shocking that it should be thought necessary to say:

It would be wise, in order that this most useful substance should not become discredited, to resist the lay suggestion, which sometimes amounts to a demand that no person should be allowed to die without having been given penicillin."

The Distressed Mind by J A C BROWN is published as No 115 of The Thinker's Library by Watts and Co at 2s 6d. This is a digest of psychiatry and a very readable comprehensive and clearly expressed one. To the reader already versed in psychology, psycho-pathology and psychiatry it all seems delightfully simple. Even the doctrines of Freud, Jung, and Adler are set out in simple terms. The danger of such digests lies in their own virtues of simplicity and clarity, for the uninstructed reader is apt to think that the whole subject is simple and easy. In justice to the author, however, it should be pointed out that he does not say so, and that the difficulties and complexities are stressed. The chapter on psychopathic states is excellent, pointing out as it does how many criminals belong to this class and how difficult it is to treat since there is almost certainly a constitutional factor in their genesis. It is as well that the public should realize that while psychiatry has an important part to play in the understanding and prevention of crime its role in the direct treatment of the criminal may be limited. In his chapter on treatment the author is wise in that he gives some detail with regard to physical forms of therapy which the general public cannot apply, but little detail of psychotherapy which the general public would like to apply. This little book, in view of its brevity, clarity, and low price, will doubtless appeal to a large public, and it can certainly be recommended if such simplifications of a complex subject are to be recommended at all.

H E Cox's *Chemical Analysis of Foods* (J and A Churchill, 24s) now appears in a third edition. It is not much enlarged but contains a considerable amount of new matter replacing some which though not obsolete is sufficiently available in former editions. This is a result of the exigencies of the present period. The new material, however, includes all the subjects that have come into prominence during the past few years, and this brings the volume up to date in the matter of vitamins and the newer official regulations governing the sale of foods. It is a most useful book to those engaged in the analytical examination of foods.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

1946 Year Book of Radiology Edited by C A Waters, M D, and I I Kaplan, M D (Pp 464 \$5 50) Chicago The Year Book Publishers, Inc 1946

The book is in two parts diagnosis and therapeutics. Includes articles on tracer chemistry, pneumography of the knee, tomography of the gall bladder, stereoscopic fluoroscopy, varieties of lobar and segmental collapse of lung, and many others.

New Aspects of John and William Hunter By Jane M Oppenheimer (Pp 188 25s) London W Heinemann 1946
An American biography of the famous surgeon and his brother.

Your Guide to the National Health Service By A D Le Vay M S, F R C S (Pp 78 3s 6d) London Hamish Hamilton 1946

An exposition and interpretation of the Act, a survey of past and present health services, and an account of the effects of the Act on doctors and ancillary medical services.

The Household Doctor Anonymous Revised (Pp 224 3s 6d) London English Universities Press 1946

A popular book whose first object is to teach the principles of healthy living. The treatment of many minor and some major diseases is also dealt with from the practical point of view.

The Use of Research by Professional Associations in Determining Program and Policy By Esther L Brown (Pp 39 25c) New York Russell Sage Foundation 1946

The utilization of research and scientific techniques by professional associations in America, with particular reference to the American Library Association.

Neue Wege in der Diagnostik und Therapie der Lues By A Rottmann (Pp 128 No price) Vienna Bruder Hollinek 1946

Summarizes the author's experience in the diagnosis of syphilis.

Surgical Clinics of North America, October, 1946 By various contributors (Pp 268 Year's subscription for 6 numbers cloth covers, 75s, paper, 55s) Philadelphia and London W B Saunders 1946

Contains three symposia: (1) Aseptic surgical technique and its application to thoracic surgery, from Duke University; (2) Gastrointestinal surgery, from Cincinnati University; (3) Genito-urinary surgery, from Tulane University and the Ochsner Clinic.

The Nature of Disease up to Date By J E R McDonagh F R C S (Pp 168 15s) W Heinemann 1946

The author develops a theory on the composition and "pulsation" of proteins and their relationship to life and disease in the soil, plants, animals, and man, with particular reference to the blood proteins.

Shall We Live or Die? By Robert Morton (Pp 114 7s 6d) St Botolph Publishing Co 1946

A survey of the apparent decline in Western culture and its causes. Suggested cures include harder living in the open air, fresh food, non-industrialized agriculture, and the reinstatement of faith in living.

Clinical Methods of Neuro-ophthalmologic Examination By A Kestenbaum, M D (Pp 384 \$6 75) New York Grune and Stratton 1946

A review of the clinical methods of ophthalmologic examination used in the differential diagnosis of nervous diseases, by the Assistant Clinical Professor of Ophthalmology, New York University. Diseases that affect the eye and the CNS in a parallel way are not considered.

Intracranial Complications of Ear, Nose, and Throat Infections By H Brunner, M D (Pp 444 No price) Chicago The Year Book Publishers 1946

An account of a quarter of a century's work in this field by the Associate Professor of Otolaryngology at Illinois University. Not intended as a textbook, the reader is presumed to be acquainted with the principles of otorhinology.

Essai d'Exploration Humaine By J F Porté (Pp 408 No price) Paris Presses Universitaires de France 1947

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 4 1947

RETIREMENT OF THE EDITOR

The issue of the *Journal* of Dec 28 was the last to go to press under the editorship of Dr Norman Gerald Horner, who retired on Dec 31 on reaching the age limit for his office. He was appointed Editor by the Council of the British Medical Association in January, 1928, when he succeeded his distinguished predecessor, Sir Dawson Williams, to whom he had acted as Assistant since 1917, after serving as a Captain in the R A M C in the war of 1914-18. Before that Dr Horner had been on the staff of the *Lancet*, which he joined in 1911 at the time of the National Health Insurance Act, his retirement from the *BMJ* coincides with the passing of Mr Bevan's National Health Service Act.

During his 19 years of editorship of the *Journal* he has seen the B M A reach out for new conceptions of a medical service, formulated before the recent war in the revised Report on a General Medical Service for the Nation, published in 1938, and the Draft Interim Report of the Medical Planning Commission, published in 1942. During his hard-working years as a medical journalist Dr Horner has witnessed not only two revolutions in medical service—troubled times indeed—but also revolutionary changes in medical science. It is hard to believe that in 1911 Hopkins had not yet published his epoch-making article on accessory food factors, and that the word "vitamine" had in that year been introduced by Casimir Funk. Insulin was discovered in 1921, and since then the science of endocrinology may be said to have grown into full adult stature. The past 10 years have seen the conquest of disease advanced an important stage further by the discoveries of the new chemotherapy. The pace of research has been breathless, and we can do no more than mention one or two milestones in medical progress, not forgetting the fearlessness and skill of the surgeon in exploring the cavities of the body, and the development of thoracic surgery and neurosurgery as compact specialties.

The rapid evolution of medicine in all its phases during the period covered by two world wars has placed a heavy responsibility upon the Editor of the *Journal*, which has not only had to serve as a scientific weekly newspaper but has also had to expound and interpret the policy of the British Medical Association. To preside over the destinies of the *Journal* during this time has been a difficult task, and one not made easier by the war of 1939-45, when the editing continued to be done in London and two changes of printer ensued on the destruction of the *Journal's* printers by enemy action in May 1941. That Dr Horner has maintained the tradition and enhanced the reputation of the *British Medical Journal* in this and in other countries has been shown among other things by its steadily

growing circulation. His services to medicine have been recognized by honorary election to Fellowships of the Royal College of Physicians and the Royal College of Surgeons. He leaves behind him a record of painstaking and conscientious work, a name for scrupulous fairness in controversy, and a reputation for a felicitous pen. His successor inherits a tradition of faithful service.

PROTEIN-REQUIREMENTS OF ADULTS

The protein requirement of adults has been the subject of research from time to time, and speculation has sometimes been based on insufficient evidence. The difficulty is that though long-term balance studies are necessary the very conditions of such an experiment, involving as it does a constancy of diet over long periods of time, may lead to an abnormal situation. Hegsted, Tsongas, Abbott, and Stare¹ recently studied the nitrogen balance in twenty-six apparently healthy adult subjects aged 19 to 50 years who were fed on diets low in protein and devoid of animal protein, and they investigated the effect of replacing part of the protein in the diet by meat, soy flour, wheat germ, and white bread. They regard it as essential that in evaluating the nutritional value of the proteins in a diet by nitrogen-balance studies the level of protein given should be sufficiently low to produce a negative nitrogen balance, and that the diet should be fed for long enough to assure a reasonably constant nitrogen output. Owing to the lag in the change of nitrogen excretion with decreases in dietary nitrogen, short periods will show negative balances that are too large. Thus if either of these two conditions is not met the determined requirement for nitrogen will be too high.

Leitch and Duckworth,² from a study of published data on nitrogen balances with varying levels of protein intake, estimated the average human requirement to be approximately 50 g per day. By what appears to have been a more rigorous selection of metabolic data Sberman and his colleagues³ estimated the requirement to be about 44 g per day for a 70-kg man. Nevertheless many of the data used by the latter investigators were collected from subjects on diets consisting almost wholly of a single protein-containing food, so the estimate may be unduly high, since in a more mixed diet the supplemental effect of the proteins would more readily make up the amino-acid requirements of the organism.

Another method of approach to this problem is based on the general finding that there is a parallelism between basal energy metabolism and endogenous nitrogen excretion (Brody,⁴ Terroine,⁵ Sorg-Matter,⁶ Smuts⁷) in all species from mice to dairy cows. This is approximately 2 mg nitrogen (125 mg protein) per calorie of basal heat expended. Terroine⁵ pointed out that if we assume that this minimum protein requirement is replaceable gramme for gramme by a completely digestible protein with a bio-

¹ *J. Lab. clin. Med.*, 1946, 31, 261.² *Nut. Abstr. Rev.*, 1937, 7, 257.³ *J. Biol. Chem.*, 1920, 41, 97.⁴ *Bioenergetics and Growth*, New York, 1945.⁵ *Arch. internat. Physiol.*, 1928, 30, 115.⁶ *Ibid.*, 1928, 30, 126.⁷ *J. Nutrition*, 1935, 9, 403.⁸ *Quar. Bull. Hlth. Org. L.N.*, 1936, 5, 427.

value of 100, then the adult human requirement is the order of 19 g, or if a protein or proteins with a biological value as low as 50 are used, then the requirement is approximately 38 g. Incomplete digestion would of course raise the requirement. On this theoretical basis the requirement of man is of the order of 20-40 g protein per day.

In the study by Hegsted and his fellow-workers the basic diet was selected to approximate in some respects to certain low-cost diets and was devoid of animal protein. White bread supplied 50% of the nitrogen, a total of 62% was supplied by cereals. Potatoes supplied 13%, and the total from vegetables was approximately 30%. The remaining 8% came from fruits. The protein intake was kept constant. The remainder of the diet consisted of butter, cooking oils, corn-starch biscuits, jelly, syrup, sugar, and sweets. The subjects were allowed these fat and carbohydrate foods freely, but everything was recorded. When meat was being tested the intake of the foods containing vegetable protein was decreased by one-third, and sufficient meat was added to supply approximately the nitrogen thus removed. The loss in calories was made good by additional amounts of the calorie supplements. The same procedure was adopted when testing soy flour and wheat germ, the vitamin and mineral contents of the diets were maintained by supplements. Certain other variations in the diets were also investigated. The authors of this investigation appreciated that owing to the shortness of the preparatory period some of their subjects were not stabilized accurately. They believe that this has the effect of placing the protein requirement at a somewhat high level.

The data from these experiments were analysed on the basis of the estimated intake at the point of nitrogen equilibrium. The daily requirement for maintaining nitrogen balance on a vegetable protein diet was approximately 2.9 g nitrogen (18 g protein) per square metre body surface—equivalent to 30-40 g protein—depending on height. When meat replaced one-third of the vegetable protein the protein requirement was found to be 17% less. The biological value of the low-protein (all-vegetable) diet used in these studies was increased from 72.5 to 80.4 by replacing one-third of the protein by meat. Those who have had considerable experience of nitrogen-metabolism studies are well aware of the very considerable day-to-day variations in urinary nitrogen excretion which can take place in some apparently normal individuals, variations not due to inaccuracies but to some instability in protein metabolism. Further considerably longer periods of collection are necessary if error resulting from the ill-defined spread of the usual time-markers for faecal collections is to be offset. Cuthbertson and Munro⁷ have also demonstrated the effect on nitrogen equilibrium of non-protein food consumed in excess of calorie requirement. Some caution is therefore to be exercised in interpreting the data of this recent work by Hegsted and his colleagues.

These requirements for protein are not to be confused with protein allowances. The latter are generally assessed as 50% greater than actual requirement so as to allow for safety. In accordance with Sherman's assessment

the League of Nations placed their allowance for men at 1 g protein per kg body weight. Determinations of the protein intake in the diets of most peoples in temperate climates indicate that the level of these nutrients tends to be fixed at roughly 10-14% of the total calories, which for normal expenditure levels is approximately the equivalent of the League of Nations allowance. It is probable that the difference between normal dietary practice and requirement is also dictated by the fact that most members of the family tend to take out of the "common pot" that measure of food which is appropriate to their energy requirements. Although school milk schemes and the distribution of milk and vitamin concentrates to priority classes are tending to alter this, the design of human diets still appears to be adapted to meet the divergent needs of the various members of the family.

CANCER CELLS IN SPUTUM

Although the technique of thoracic surgery has been highly perfected, Tudor Edwards¹ found that he was able to perform a pneumonectomy in only 66 out of 1,016 cases of bronchial carcinoma which he had seen. The importance of methods for the early diagnosis of the condition is more than apparent. Present methods of diagnosis consist of a consideration of physical signs, symptoms, skiagrams, bronchographic and bronchoscopic investigation with histological examination of the sections obtained, direct aspiration of the tumour through the chest wall, and thoracotomy. Little attention has been paid to the simple procedure of microscopical examination of the sputum.

As early as 1860 Beale² described masses of malignant cells in the sputum from a case of advanced pharyngeal carcinoma, Betschart³ in 1895 described four cases of malignant disease of the lung in which pieces of tumour were expectorated, and in 1913 Weller,⁴ in an analysis of ninety cases of primary bronchial carcinoma, stated that malignant cells had been found in the sputum from four cases. Nevertheless this form of investigation was not properly developed until Dudgeon and Wrigley⁵ in 1935 published a detailed account of a wet-film method for the examination of the sputum for evidence of malignant growth. Since then considerable success has been reported in many countries—70% in Russia,⁶ 86% in Denmark,⁷—and enthusiastic reports have been published in Latin America.⁸

In England first Dudgeon,⁹ then Barrett,¹⁰ and then Bamforth¹¹ reported the results from St Thomas's Hospital. In the first paper an account was given of 102 cases examined, of which fifty-six were eventually proved to be cases of malignant disease, out of the fifty-six a total of forty-three, or 76%, were diagnosed by examination of sputum. The second paper added 119 positive cases, and the third a further 113. Sambrook Gower¹² used the method in ninety-three cases of proved or probable carcinoma at the London Hospital and obtained a positive result in 64.3%. He drew attention to the fact that a high proportion of the positive cases were of the squamous cell

type, though these probably only form a third of the cases of carcinoma of bronchus. Gloyne,¹³ in a paper on the cytology of sputum, also commented on the greater frequency with which squamous-cell growths were detected in the sputum and suggested that it was due to early breaking down of these growths, whereas oat-cell carcinomata do not ulcerate till a late stage and do not readily break down.

This year also a report has come from Herbut and Clerf¹⁴ in Philadelphia on the examination of bronchial secretion for malignant cells. They chose bronchial secretions rather than sputum because they consider that they are more concentrated, and that expectoration of sputum does not occur until late in the disease. Bronchoscopy is now performed as a routine in every case of suspected pulmonary cancer, and material which comes from the area of the suspected tumour is more likely to contain cancer cells than are the more dilute secretions found in the trachea and the even more dilute sputum. They claim that in thirty consecutive cases of primary pulmonary carcinoma cancer cells were demonstrated in the bronchial secretions of twenty-two, or 73%. Bronchoscopy was negative in seven of these cases. Sputum was examined from five cases in which cancer cells were present in the bronchial secretions and in only one were neoplastic cells found.

Bamforth, in his article¹¹ in *Thorax*, reported also that a number of specimens of pleural fluid were examined between December, 1937, and March, 1946 and that in thirty-one cases a positive diagnosis was made by examination of the pleural fluid. In thirteen cases considered to be primary carcinomata of the lung no evidence of neoplasm was found outside the chest. Obviously a case with a pleural effusion is inoperable, but it is frequently difficult to establish the diagnosis with certainty, a simple method which can achieve this would be of the greatest practical value.

PLEURAL GAS ANALYSIS

Analysis of the pleural gases in cases of pneumothorax often yields useful information, and the pioneer work of Coryllos has done much to show the possibilities of this method, particularly in the clinical diagnosis of bronchial fistulae. A recent paper by Ornstein, Herman, and Friedman¹⁵ serves to emphasize some of the many problems connected with the behaviour of the pleural gases which still remain unsolved. These authors consider that in the past too little attention has been paid to the role of the pleura in affecting gaseous exchanges, and they challenge the diffusion theory which most physiologists have advanced to account for the absorption of gases from the pleural cavity. According to this theory the oxygen and carbon dioxide in the pleural cavity reach equilibrium with the corresponding gases in the venous blood, thereby raising the partial pressure of the pleural nitrogen above that in the capillaries. The nitrogen therefore diffuses out of the pleural cavity and thus raises the partial pressures of the pleural oxygen and carbon dioxide above those in the venous blood. The cycle then repeats itself until all the gases are absorbed.

In a large series of observations Ornstein, Herman, and Friedman found wide variations in the oxygen and carbon dioxide content of the pleural gases in different cases, although the values were usually constant for the same individual. Moreover, the partial pressures of these gases were often different from the theoretical pressures of the corresponding gases in the venous blood. The authors conclude that the pleural oxygen is not in equilibrium with that

in the venous blood. They also found that the volume per cent of carbon dioxide in the pleural cavity was remarkably constant in individual cases, whereas the diffusion theory suggests that the level should vary at different times after a refill. They infer that the pleural gases are in equilibrium with the pleural tissues rather than with the venous blood, and that oxidative processes in the pleura are responsible for the high carbon dioxide and low oxygen values so often encountered, and for the outpouring of carbon dioxide after pleural lavage with oxygen. The absorption of nitrogen still remains to be explained, and they suggest that the expanding lung may exert sufficient pressure on the pleural gases to raise the partial pressure of the nitrogen to a level which will ensure its absorption.

There are many weak links in this chain of reasoning. The fallacies of theoretical estimation of the gases in the venous blood are well known, and we have no means of determining the values for the pleural circulation. Again, the pleura itself may act as a variable resistance and under certain conditions, such as pleurisy, may impede the passage of gases to and from its capillaries. Finally, there is no evidence that the expanding lung exerts any pressure on the pleural gases. However, this paper serves a useful purpose in drawing attention to these problems of the pleura and to the possibilities for further research based on gas analyses.

Another observation reported by these investigators will interest many tuberculosis workers. In five cases they measured the volume of the pleural cavity twenty-four hours after the induction of a pneumothorax, and in every case the volume was greater than that of the air injected. They conclude that the excess air must have escaped from a puncture in the lung. Tchertkoff¹⁶ propounded the theory that the lung was always punctured during the induction of a pneumothorax and that the initial pleural space was produced in this way. Most workers believe that a blunt cannula can be introduced between the pleural layers without puncturing the lung, but this requires investigation. It should be relatively simple to find out by pleural volume estimations how often the lung is punctured when using different induction techniques. Such information would have an important bearing upon the design of pneumothorax needles.

MYOCARDITIS IN MUMPS

Cardiac injury is not usually regarded as a common complication of mumps. As with any other acute infection convalescence is sometimes retarded by the presence of slight cardiac dilatation, with perhaps a soft systolic murmur at the apex which would usually be regarded as non-specific in origin. Apart from Pujol's¹⁷ records of three cases of myocarditis where mumps seemed the only exciting cause, there is little reference to the complication and none to a series of cases studied systematically for its occurrence. Rosenberg¹⁸ recently observed two patients in whom there seemed no doubt that mumps was the exciting cause of heart block, and he was therefore prompted to make a careful study of the heart in a group of adults suffering from the disease. These two cases developed typical heart block confirmed by electrocardiogram (E.C.G.), one on the seventh and the other on the fifteenth day of illness. Both patients complained of retrosternal or precordial pain and experienced palpitations or dizziness. After a day or two the first patient developed a harsh systolic murmur at the apex which gradually diminished in intensity, and eight days after the onset of

symptoms the ECG was normal. The other patient, however, continued to show abnormal tracings until the seventy-seventh day of illness.

An electrocardiographic study of one hundred and four adults with mumps was then undertaken. Repeated examinations of forty-six of them were made at 2-4-day intervals. Abnormal records were obtained from 15%. There was no specific ECG pattern, the most common abnormality being a change in the form of the P wave, or a prolongation of the P-R interval. Fourteen of the patients showed more than one abnormality. Apart from one case all the changes occurred between the fifth and tenth days of illness, that is, at the same time as one expects to find other evidence of systemic dissemination of the virus. Subjective complaint was made by only four patients, in the others recognition depended entirely on the electrocardiographic examination.

The pathological nature of such changes must remain a matter of conjecture, but the findings raise the interesting question as to how far they are specifically caused by the virus. There is no doubt that myocardial damage may follow a severe virus infection such as influenza, and Finland and his colleagues¹⁹ have reported two examples of non-bacterial myocarditis in which influenza (virus A) was the aetiological agent. It seems more likely, however, that the abnormalities reflect a non-specific myocardial lesion which might be a part of any acute infection. Indeed, Rosenberg avers that he has encountered similar changes not only in rheumatic fever but even in such mild infections as rubella. Watson, Rothbard, and Swift²⁰ recently recorded a study of one hundred and ten patients with scarlet fever who were investigated in a manner very similar to that of Rosenberg's study. In twenty-two instances they found abnormal ECG patterns—most commonly inversions of the T waves and indications of transient partial heart block. In the majority of their patients the abnormalities were detected much later (tenth to fifty-sixth day of illness) than in the mumps cases, but like them many made no subjective complaint. Since they were dealing with a streptococcal infection it was natural to interpret their findings in the light of rheumatic fever and to consider that the fundamental tissue injury was the same in both. Rosenberg rightly argues, however, that delayed conduction time should not be regarded as a specific indication of rheumatic fever and that a recent acute febrile illness may induce ECG changes which do not have the same serious significance.

The old clinical conception of myocarditis as a not uncommon complication of acute infections seems to gain some recognition from these findings. Is it possible that they may also explain the recrudescence of rheumatic fever sometimes seen in the course of an infection such as pneumonia in which haemolytic streptococci do not appear to have played a part?

SYMPTOMLESS GLANDULAR FEVER

It was formerly said that glandular fever was seen more often in medical students and nurses than in any other classes of the community. This unusual incidence was attributed to the fact that the proximity of such patients to the laboratory attracted the attentions of the haematologist. Now the spread of institutional medicine and of clinical pathology has made it clear that glandular fever is not only a common disorder but one on which current views need to be recast.

Tidy²¹ recognized glandular, febrile, and anginose types of the disease. Jaundice, meningo-encephalitis, parotitis,

and a thrombocytopenic haemorrhagic state are noted by Bernstein²² as acknowledged complications. But the epidemics described by Halcrow, Owen, and Rodger²³ in 1943 and by Van der Meer, Lutterloh, and Pilot²⁴ in 1945, have stressed a new aspect. The first started in an E.M.S. hospital, which was thereupon closed to further admissions. The blood of all patients in hospital and of some of the medical and nursing staff was examined, of these 296 persons 125 presented the clinical and haematological picture of glandular fever, and a further 165 had the characteristic blood and serological changes without symptoms or physical signs of the disease. The second group of authors made similar observations on an American Army unit of 600 men from which several cases of glandular fever had been admitted to hospital. Blood films from 522 healthy men were examined, in 217 "abnormal cells resembling typical mononucleosis cells" were seen. The agglutinins for sheep's erythrocytes were titrated in the sera of 74 of these men and figures above 1/56 found in 13.

Study of the epidemic in the E.M.S. hospital has provided conclusive proof that the haematological and serological changes regarded as characteristic of glandular fever can exist without any clinical signs of ill-health. The second paper is less well documented and in many cases the proportion of abnormal cells was below 5%. The familiar problem arises of whether the "glandular-fever cell" is specific in its diagnostic import. Such cells were found by these authors in percentages of 1-20 in blood films from 110 patients admitted to hospital with other complaints, and Downey and Stasney,²⁵ Warren,²⁶ and others have described their presence in a variety of unrelated conditions. Thus it seems unjustified to regard the finding of a few "glandular-fever cells" in the blood film as necessarily indicating glandular fever. The absence of heterophil agglutinins is of little significance unless the test is repeated frequently, for Himsworth²⁷ has reported an example in which the titre did not rise to a diagnostic level until eleven weeks after the onset. Even with these reservations Van der Meer, Lutterloh, and Pilot have confirmed the existence of this asymptomatic form of the disorder described by Reyeisbach and Lenert²⁸ and the British observers.

Emil Pfeiffer's²⁹ concept of *Drusenfiebers* must now be expanded to include not only the variants which most clinicians have come to recognize but also this symptomless haematological disturbance. Moreover the experience of Halcrow, Owen, and Rodger suggests that the accepted view of its low infectivity must be revised, for of the sample of the population at risk which they examined 97.9% showed evidence of the infection.

ABSTRACT JOURNALS

Owing to printing difficulties it has, unfortunately, not been possible to publish *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynaecology* on Jan 1 as advertised. Both journals should be published next week.

We regret to announce the death of Sir Richard Cruise, G.C.V.O., Surgeon-Oculist to King George V and Queen Mary and consulting surgeon to the Royal Westminster Ophthalmic Hospital.

THE FIRST ADMINISTRATION OF ETHER

Centenary Commemoration at University College Hospital

On Dec 21 1846 at University College Hospital London, the first public operation under an anaesthetic to be performed in Europe was carried out by Robert Liston. The patient was a Harley Street butler aged 36, who came for amputation of the right leg above the knee. At 2.25 on that day he was brought into the operating theatre, he breathed ether vapour for between two and three minutes, and the effect was such as to cause complete insensibility to pain, although consciousness was retained and questions were answered. Liston performed the complete operation in less than half a minute during which not the slightest groan was heard from the patient nor was his countenance at all expressive of pain.

To commemorate this event a gathering took place at University College Hospital on Dec 21, 1946 at which Dr MASSEY DAWKINS gave a short address. The original operating table with the holes through which the straps were drawn to restrain patients in pre-anaesthetic days, a model of the original inhaler and various contemporary sketches and portraits were exhibited and a copy of the case notes of this successful amputation was handed to every visitor.

Dr Dawkins said that an attempt had recently been made by Scotch friends to claim for a hospital in the North the honour of the first ether administration in the Old World but the evidence was scanty (*Journal* Oct 26, p 621) and the occasion was not in any sense a public one. Some idea might be obtained from Sir Rickman Godlee's biography of Lister of the state of pre-anaesthetic surgery at University College Hospital. The three senior surgeons operated only on Wednesday afternoons and with such celerity that that time was sufficient for all the operations of the week apart from emergencies. Patients requiring amputations were asked at the doors of the theatre whether they would have their leg off or not and if they said 'Yes' no heed was taken of any subsequent change of mind. Patients at first frequently refused to face the ordeal, then became resigned only many of them, to engage in a useless resistance at the last moment.

In October 1846 the discovery of ether anaesthesia was announced in America. Liston witnessed its demonstration at the Royal Medical and Chirurgical Society where Matthew Duncan was a volunteer. Liston was a surgeon of great skill and of forceful character with remarkable dexterity in the use of cutting instruments. The operating theatre in which he worked was a semicircular apartment about 40 ft (12 m) across with sharply rising tiers of seats for the students. It contained a small basin about the size of a soup plate in which the surgeons washed their hands—sometimes even before the operation—and there were pegs from which hung the blood-stained frock coats of the staff. Actually the first English operation performed under ether anaesthesia was a dental extraction carried out by Mr Robinson, a dentist of Gower Street.

Liston's theatre had a noteworthy company including Sir Russell Reynolds, Sir John Erichsen and the future Lord Lister. Liston gave a short address describing the American discovery and the advantages to be hoped for added a word about the weak condition of the patient and appealed for quietness and consideration. The patient was brought in with a handkerchief covering his face. Ether induction took place quietly, and in twenty-six seconds the limb was off. The patient rising as from ordinary sleep then said 'Take me away. I cannot have it off. I must die as I am' and could hardly believe when it was proved to him that the limb was already amputated. He went on without interruption to a good recovery and was discharged from the hospital on the following Feb 11. Sir John Forbes, one of the spectators said that he never felt so near to falling on the floor in his life as he did when he witnessed the operation. Everybody was pale and silent except Liston himself who was flushed and excited and could scarcely command himself to speak. When after it was over he broke the silence and said 'Gentlemen' he almost choked. According to Sir Russell Reynolds's account he said before starting 'Gentlemen we are going to try a Yankee dodge for making men insensible. This man's leg has to come off above the knee and my friend Mr Squire

is going to give the ether so that the man will not feel it.' The ether in those days was not as pure nor the apparatus as handy as now so perhaps Liston was a little impatient to get on with his work. When Squire said he was ready, Liston's knife flashed in the air. 'I took out my watch' said Reynolds and the leg was on the floor in twenty-six seconds. Liston turned to the company 'This Yankee dodge beats mesmerism hollow.'

There was a curious incident of a student (or by some accounts a hospital porter) named Sheldrake, a man of powerful build, who volunteered to be anaesthetized in the theatre but after half a minute's administration sprang from the table, felled the anaesthetist with a blow, swept aside the assistants and tore up the gangway, scattering the students like sheep. The second patient on whom an operation was done under anaesthesia was an out-patient whose toenail was removed. On the same night, in a letter to a friend, Liston began with the words of St Paul, 'Rejoice, and again I say, rejoice.' At dinner that evening he insisted on anaesthetizing his assistant. The assistant said afterwards that when he was about half under he heard one of the ladies say 'Mr Liston for God's sake stop, you will be the death of this young man.' He did stop but the assistant felt the pressure of Liston's hands on the lobes of his ears for a day or two.

The lay press took no account of this historic happening until Christmas Day, when it was mentioned in the *Daily News* sandwiched between paragraphs about the lateness of the Birmingham mail and a fracas of bedmakers and students at Cambridge. The *Times* did not notice it until Jan 4 1847. The change in surgery consequent upon the introduction of anaesthesia was a very gradual one. No striking new operations were introduced, no new fields opened up, operations were still performed at breathless speed and students still saw the surgery of pre-anaesthetic days robbed only of its most shocking feature, that of the pain inflicted. But the records of University College Hospital showed no cases of excision of the knee between 1830 and 1850 while in the next four years there were twenty-one cases. Ether was still the safest anaesthetic for general use and despite the advances in other forms of anaesthesia the average yearly consumption of ether was now more than half a ton at each of the large London hospitals.

Dr E. A. BARTON whose father then twenty-two years of age was at University College Hospital and present on the occasion added a few words. He recalled the smallness of the old theatre how the students in their tiered seats looked down upon the patients. His father had told him that in the pre-anaesthetic days the one part of their training which the students could not stand was the surgery course, which was made dreadful by the shrieks and screams coming from the operating theatre and echoing through the hospital. The wooden table on which the operations were done had been rescued from a lumber room and was now a treasured museum piece at the hospital.

HEALTH ADMINISTRATION IN THE CITY OF LONDON

The development of health services in the City of London was the subject of interesting speeches at a luncheon of the Corporation health committee on Dec 19 when a presentation was made to Sir George Elliston on the completion of his third term of office as chairman of the committee.

Sir ALLEN DALEY, President of the Society of Medical Officers of Health, pointed out that the Corporation had been issuing sanitary regulations as far back as 1281 and had continued to develop their health services from that time onwards. But the outstanding event in the health history of the city had been the appointment by the Corporation in 1848 of Sir John Simon as their first medical officer of health. For once London had to yield pride of place to Liverpool, who had appointed the first of all medical officers of health the previous year.

From Simon onwards the City could be relied upon to pick winners for its chief health officers. After seven years' service with the Corporation Simon had become successively medical officer for the Central Board of Health and for the Privy Council and the first medical officer of the Local Government Board. He had therefore been the first in line of the seven medical officers who had filled the City post now held with

such distinction by Dr Charles White. He had also been the first in line of the chief medical officers of the Ministry of Health.

Hygienist and Surgeon

Simon had been not only a great hygienist but also a distinguished surgeon on the staff of St Thomas's Hospital and sometime President of the Royal College of Surgeons. His reputation among scientists had secured his election as a Fellow of the Royal Society.

During his seven years in the City he had coped with an outbreak of cholera (1854). He had laid the foundation of the work of a public health department as we knew it to day, but naturally with emphasis on bad environment. He had started house-to-house inspection and the registration of tenement houses, his had been the first annual report of a medical officer of health. His reports had been models of clarity and good sense. He had asked for power to control nuisances, unhealthy industries, the adulteration of food, and the sale of poisons. He had recommended that there should be one Minister of the Crown for all health purposes, but not till 1919 had we had a Minister of Health. On leaving the City he had expressed 'grateful recollection of the years during which I have been a local officer of health'. The citizens, he had said, had always treated him with favour and confidence notwithstanding all he had had to preach to them. In 1885 all the vestries in London had been required to follow the example of the City and appoint an M.O.H. and Simon had been very gratified that so many distinguished doctors had sought these posts.

The Corporation during the past 100 years had been responsible for much pioneer work in the City. Their chairman, Sir George Elliston, had claimed that they cared for the citizens from the cradle to the crematorium, and it was true that the City had set a high standard in the matter of infant welfare work just as they had been among the earliest municipal bodies to provide a crematorium. They had set an early example in securing open places for the recreation of the people, they had developed highly efficient port health services, through their markets and inspections they had done much to safeguard the food supplies of Greater London, finally, they had maintained through the centuries close connexion with the five royal hospitals.

Bart's and the City

SIR GEORGE AYLWEN replying to the toast, said it was a matter for pride that St Bartholomew's, founded in 1123, had for 8½ centuries on the same site continued its benevolent work of tending and healing the sick. The history of the hospital was inextricably interwoven with the history of the City. It had been the citizens of London who, with their own hands, under the guidance of Rahere, had built the first St Bartholomew's, and who had successfully petitioned Henry VIII to restore to them the ancient Foundation which he had suppressed. The legal title of the hospital was still 'The Mayor and Commonalty and Citizens of London, Governors of the House of the Poor, commonly known as St Bartholomew's Hospital'. In early days the City Corporation and the hospital had not always been on good terms. In 1559 the governor had complained that the Lord Mayor was wrongfully withholding their water supply. In 1697 we found the hospital governors protesting vehemently to the City aldermen about a matter of £7,500—no mean sum in those days—which the aldermen had seemed disinclined to pay until the court of chancery had insisted that they should. In 1775 the Common Council had attempted to induce the tenants of the hospital to pay their rents to them instead of to the hospital governors. Since then times had changed, and he was proud to think that to day and for many years past, the hospital's relations with the City Corporation had been an object lesson to local authorities and voluntary hospitals alike.

Partners in Welfare

The hospital regarded it as a privilege to co-operate with the Corporation in providing those services which were essentially the responsibility of the medical officer of health. The Corporation in their turn regarded themselves as fortunate to enjoy the services which only a great hospital like St Bartholomew's could adequately provide. There were no arguments, no

troubles, no friction, no questions of prestige, just a sincere and mutual desire to secure for the patients the best possible treatment that medical and nursing skill could provide. He needed only to mention some of the services the hospital so willingly rendered the City. Since 1915 there had been established at Bart's the City's tuberculosis dispensary, and during these thirty years just over half a million attendances had been recorded. For nearly thirty years, first in Golden Lane and subsequently in the hospital, the governors had undertaken the provision of a special treatment centre for City patients suffering from venereal disease. From 1932 onwards the hospital's infant welfare clinic had been made the subject of an agreement with the Corporation whereby City mothers and babies could attend there at all times for attention and advice.

These and many other activities it had been the privilege of the hospital to undertake. That they had been successful there could be no doubt. But that success had been due not only to the part played by St Bartholomew's, it had been due just as much to the help and co-operation received from the Corporation and its medical officers. Speaking as treasurer of Bart's it might be hoped that under the National Health Service there would be left to them the opportunity and the privilege of continuing, with the Corporation as their partners, a service which had proved itself so outstandingly successful in the past.

REHABILITATION AND OCCUPATIONAL THERAPY CENTRE AT BROMLEY

A Rehabilitation and Occupational Therapy Centre at Bromley and District Hospital in Kent was opened on Dec 14 by Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health. Dr Talbot Rogers stated in some introductory remarks that the hospital had received help from the Ministry in the form of equipment and of postgraduate facilities for those who would work at the centre. When fully started in the new year the department would employ eight physiotherapists. It was equipped to give all forms of electrical treatment except deep x-ray therapy. In the remedial gymnastic department emphasis would be laid on group methods in treatment. Patients would come to the department from the hospital or from other hospitals or be sent directly by local doctors. Dr D. B. Whitlock and himself would supervise and co-ordinate the department to which doctors would have full access and would be informed of the progress of their patients. Two ways in which the department expected to extend its activities were the provision of evening clinics and the use for mobile physiotherapy of a general purposes car which had been given to the hospital.

Sir Wilson Jameson, after an appreciation of Dr Talbot Rogers's work on the Medical Advisory Committee of the Ministry and a word of praise for the Bromley Hospital as one of the best general practitioner hospitals in the country, went on to say that the sphere of usefulness of hospitals had tended to be limited to the more critical phases of ill health, and too little regard had been paid to means of preventing physical breakdown or to the methods of rehabilitation. Great changes were likely to take place, however, and it was good to see Bromley well in the van.

"It should increasingly become the practice for patients requiring specially expert medical and nursing skill to seek such help in the well equipped hospital of the future rather than in their own homes. The shortage of domestic labour and a growing appreciation of the importance of the ancillary medical services are already resulting in more numerous applications for treatment in hospital, and as soon as more adequate staff and accommodation are available hospital services will be more and more in demand."

The hospital of the future, Sir Wilson Jameson continued, would no longer be preoccupied with what might be termed the medical stage of ill health but would concern itself to an increasing degree with the primary and with the final stages—that is to say, with methods of prevention and of rehabilitation. In the past those patients who were debilitated by serious illness or unable to return to their former employment on account of severe disabilities left hospital in too many cases with little more than a recommendation that they were fit only for light work. Yet numbers of them if only they had been taken in hand in time and provided with the necessary medical rehabilitation and vocational guidance could have been saved from

The B D H range of sex hormone products includes preparations for the treatment of all forms of gonadal deficiency. Synthetic oestrogens also are available.

24-HOUR CONTROL

The characteristics of 'Wellcome' Globin Insulin (with Zinc) are adapted to the physiological needs of the patient — maximal effect during the day, diminishing effect during the night. This improved type of modified insulin (developed in The Wellcome Research Laboratories, Tuckahoe, New York) is available in strengths of 40 and 80 units per c.c., each in 5 c.c. phials.

Vitamin Therapy its uses and limitations

CONGESTIVE FAILURE with oedema

The combined effects of poor absorption distribution and utilisation of nutrients consequent on a failing circulation frequently cause deficiencies of the vitamin B complex which tend to accelerate the development of congestive failure. While vitamins cannot be expected to affect valvular disease they may bring about a reduction of oedema and an improvement in appetite and general well being the production of which is one of the chief aims in treatment.

REFORTISS

B complex capsules

Each capsule contains

Aneurin hydrochloride 10 mg	Riboflavin 10 mg
Nicotinamide 150 mg	Pyridoxin 0.5 mg

Product of Vitamins Limited

Upper Mall, London, W 6

For Surface Anaesthesia

EYES

NOSE

THROAT

'Decicain' penetrates the mucous membrane deeply and produces rapid and prolonged surface anaesthesia. It is non-irritant, is stable in solution and can be sterilized by boiling.

USUAL DOSAGE OF DECICAIN

Ophthalmology 0.5 per cent solution of 'Decicain' serves for a wide variety of procedures. It does not dilate the pupil.

Rhinolaryngology Up to 1 c.c. of a 2 per cent solution is adequate for puncture and irrigation of sinuses, cauterization and removal of polyps, and for examination of the throat.

'DECICAIN'

NOTTINGHAM ENGLAND

chronic invalidism. It was in this respect that hospitals possessing modern rehabilitation departments could render such valuable additional service to the community. Physiotherapy and rehabilitation would form an essential part of the hospital and specialist services of the future. He added that a modern rehabilitation department should, wherever possible, be open in the evening as well as during the day. It should also be provided with its own almoner or social worker. It was important also that such a specialist service should never be divorced from the general practice of the neighbourhood. Hospitals which were already experimenting in this form of community service were meeting an astonishing response to their endeavours. One hospital which served a somewhat similar area to that of Bromley reported no fewer than 500 patients attending daily in its physiotherapy and rehabilitation department. In 1943 there were some 48 hospitals in England and Wales possessing all facilities for active rehabilitation, the latest figure he could give was 204, with a further 129 having partial facilities.

'The principle of general practitioner hospitals and departments is now widely accepted—always with the proviso that such a hospital or department should form part of a bigger scheme with suitable links with a larger parent hospital, preferably of teaching hospital standard.'

Bromley provided an excellent demonstration of the importance of having hospital facilities readily available to the general practitioners of the area.

MEDICAL PHOTOGRAPHY

Increasing interest is being taken in the use of photography and cinematography for record and teaching purposes, and it has been found particularly valuable in the medical sciences. In accord with this the Institute of British Photographers has decided to allot one part (Section 4) of its final examination to medical photography. Candidates must have passed the Institute's intermediate examination, and therefore be acquainted with general photographic theory and practice, before sitting for the final, for which is required not only a higher standard of photographic knowledge but also a knowledge of such subjects as human anatomy and physiology, medical terms and their significance, the recognition of the regions and tissues of the body from photographs and skiagrams, and also the more general topics of medical etiquette, relations between photographer and doctor, nurse, and patient, the problems of working in operating theatres, and the risks of infection. Since much of the medical photographer's work consists of record photography, he must learn standardization of technique and record filing.

The qualified medical photographer must have a wide range of technique at his command. With the improved materials now available infra-red, ultra-violet, and fluorescence photography may be required, and he may also carry out miniature radiography, photomicrography, and stereoscopic photography.

The Scientific Film Association, 34, Soho Square, London, W1, was founded in 1943 to provide information on and promote the use of scientific films. Membership is open to private persons, academic institutions, and commercial firms. It has issued several lists of films of medical interest, the latest being a *Catalogue of Films on Anaesthesia*, which includes notes on about twenty-five films.

A detailed account of each film is provided—running time, gauge, where made and by whom, etc—but the most interesting feature is an 'appraisal' that comments on the qualities of each film from every point of view—photographic, scientific, and educational. The Association has a viewing panel, which appoints appraisal groups of a 'considerable size,' to examine films selected by the appraisal committee. The constitution of these groups is kept as wide as possible so that every aspect of the film shall be judged, and they include medical specialists, house-men, nurses, students, photographers, and laymen. The result is admirable appraisals seem to be entirely objective, and, indeed, sometimes severe. If a film is practically valueless in the opinion of the appraisal group the fact is recorded.

The whole range of anaesthesia is dealt with in this series—local, spinal, intravenous, and inhalation, and there are films on operative shock, the handling of the patient, and respiratory and cardiac arrest.

Reports of Societies

CARCINOMA OF THE STOMACH

A symposium on carcinoma of the stomach was held at two joint meetings of the Radiological Section of the Royal Society of Medicine and the British Institute of Radiology on Dec 13 and 14. The chairmen at the sessions were Dr S WHATELY DAVIDSON, president of the Section of Radiology, and Dr H W SMITHERS, president of the Institute.

Radiology and Gastroscopy

Dr J A GROUT discussed the various sites and radiological signs of carcinoma. The radiologist should be able to distinguish between the ulcer and a cancerous lesion. The mucosa and the peristaltic waves, which only at the later stages stopped at the obstruction, needed careful examination.

Mr H W RODGERS said that radiology and gastroscopy were complementary methods of examination. The principle that gastroscopy should follow x-ray examination was important. Gastroscopy was contraindicated in gross deformity of the oesophagus, spinal curvature, atrophy of lining mucosa, and if x rays demonstrated an advanced carcinoma. Gastroscopy was of value in clinically suspect cases which were obscure or negative radiologically, but the technique had definite shortcomings in not showing the whole area of the stomach. Of carcinomata, 10% were diagnosed by gastroscopy, but the whole position concerning gastric carcinoma was disquieting and every effort must be made to find precancerous lesions. Gastroscopy had made the diagnosis of early cases possible.

Pathology and Surgery

Prof M J STEWART said he was impressed by the malignancy of the scirrhous cancer of the stomach, which recurred. The fact of invasion of the lymphatic glands, not its extent, was the important point in ultimate prognosis. Concerning the spread of carcinoma of the stomach, it was remarkable how seldom it transgressed in the duodenum, when it did so it was always by submucous extension, and such cancers made their way back to the surface, giving the appearance of two independent cancers. He gave his own figures covering a twenty-year period, including over 700 cases. One interesting point brought out was the positions of chronic ulcer, ulcer cancer, and primary cancer in 358 surgical specimens.

	Chronic ulcer %	Ulcer-cancer %	Primary cancer %
Pyloric end	57	29	84.5
Lesser curvature	94.3	71	10.7
Rest of stomach	0	0	4.8

For Mr HERMON TAYLOR the outstanding clinical fact about cancer of the stomach was that, in itself, it was a symptomless disease, a large tumour might develop without being suspected by the patient. Bleeding of a sufficient degree to cause alarm was uncommon and pain was a later symptom. Unless the growth was in a position to cause obstruction there was no compelling reason which drove the patient to the doctor. The potential significance of the minor symptoms and correction of the misconception that cancer need only be postulated if symptoms failed to respond to treatment were important. Pyloric growths, as they might give rise to obstructive vomiting, were generally recognized earlier than the less common tumours of the body of the stomach. Ulcers which underwent malignant change were mostly situated near the pylorus, and the danger in these cases was that a new symptom might be regarded as part of the already established general picture. Persistent minor dyspeptic symptoms arising *de novo* in a patient over forty, or persistent vomiting in a patient with known ulcer, must be investigated for malignant disease before treatment was applied. Of thirty-eight consecutive patients many of whom were diagnosed early by gastroscopy, no fewer than eleven showed histological evidence of their lesion having arisen in a chronic ulcer.

By modern radiological technique, supplemented where necessary by gastroscopy, the diagnosis of carcinoma of the

stomach could be established as a fact and not an opinion. An unequivocal filling defect shown by x rays needed no gastroscopic confirmation. But radiology and gastroscopy failed to estimate the operability of the lesion, demonstrating only its mucosal aspect, and giving no indication of lymphatic involvement. The question of operability could be decided finally only by the surgeon's hand within the abdomen. Adequate extirpation of the growth could be achieved in a large proportion of cases only by a wide dissection, as was illustrated by 17 cases of radical removal for gastric carcinoma in which one or two of the contiguous viscera were removed with the stomach. Of these 7 died as a result of the operation, but of the 10 survivors 8 were still alive after two or three years.

Radiotherapy

Dr G C FAIRCHILD and Mr ALAN SHORTER presented a joint paper on radiotherapy. They described the technique for direct irradiation of deep seated tumours exposed temporarily at operation. Intensities of 3,000 r in three minutes were used and radiation of the normal viscera so far as possible avoided. Of 15 cases of inoperable gastric cancer treated by direct radiation, the growth in 7 was so extensive that the radiation could be palliative only, among these the longest period of survival was six months. In 8 cases in which the growth was limited to an area which could be irradiated, the period of survival after treatment in one case was twenty-four months, in another fifteen months, and in the others shorter periods.

Dr D JENNINGS said that carcinoma of the stomach was the most important form of malignancy in Western civilization. The total yearly incidence of carcinoma of the stomach in persons under the age of 70 was 8,500. Of these cases 7,000 were referred to hospital, of these again between 3,000 and 5,000 were referred to surgeons, on these between 1,000 and 3,000 laparotomies were carried out, from 300 to 1,000 underwent a gastric operation, from 200 to 500 survived gastrectomy, and from 40 to 100 were 10 year survivors.

THROMBOSIS

A meeting of the Section of Pathology of the Royal Society of Medicine was held on Dec 17, with Dr A B ROSHER president, in the chair. The members of the Surgical Section had been invited.

Pathological Post-operative Thrombosis

Mr H J B ATKINS opening from the surgical side, said that thrombosis as a post operative complication was increasing and there were many problems connected with it which the pathologist would be able to help the surgeon to solve. Thrombosis, of course, was a natural and physiological accompaniment of any operation. By post-operative thrombosis was not meant that natural occlusion in the veins at the site of operation which would normally occur, but a thrombosis which tended to spread or which appeared remotely. A question at issue was whether pathological post-operative thrombosis was due to a spread by continuity of natural thrombosis. He had analysed the records of a series of cases of post operative thrombosis occurring at Guy's Hospital between 1921 and 1925, and during that time there were two cases of axillary vein thrombosis—one after a gastrectomy and the other after a prostatectomy—and two cases of left femoral vein thrombosis following radical mastectomy. An argument which was put forward to show that thrombosis in the leg veins was a spread from the site of operation was that thrombosis was extremely rare when the abdomen had not been opened. After laparotomy there was diminution of the respiratory excursion, and this would lead to a slowing of venous return, which was an important factor in the causation of thrombosis. Pelvic operations were peculiarly liable to be followed by post-operative thromboses, this suggesting that thrombosis extended from the operation site. But here age incidence should be taken into account. Pelvic operations were performed more commonly on patients getting on in life who were more liable in any event to thrombotic complications. Mr Atkins felt that the continuity theory as an explanation of post operative leg thrombosis should be discarded.

Why did the remote thrombus form? An operation occasioned various changes in the blood—an increase in the platelets and fibrinogen content—two factors closely connected with blood coagulation—and also a slowing of the blood stream consequent upon recumbency. Again there was the possibility of infection which might cause an endophlebitis predisposing to thrombotic complications. Why did thrombosis so commonly occur in the left leg? Venous circulation was sluggish after an operation, and more sluggish on the left side on account of pressure, perhaps by the sigmoid colon and iliac vessels. Anti coagulation therapy protected the patient in a very large measure against the development of pulmonary complications. All that such therapy could do was to prevent the development of fresh thrombi, it could not influence the thrombus already present, and it looked as if it were only the freshly formed thrombi which were likely to cause pulmonary embolus. What clinicians would like to know from their pathological colleagues was how fresh the thrombus must be to cause pulmonary manifestations. Heparin and dicoumarol were agents which prevented thrombus formation but the former had certain disadvantages and the latter some dangers. On the other hand, it was known that as soon as the patient got up the danger of the occurrence of thrombus was very slight. Could the duration of anti coagulant therapy be shortened with safety?

Pathology of Primary Thrombosis

Dr R H D SHORT described an imaginary post mortem examination of a case in which death had occurred from pulmonary embolism ten days after an operation. On opening the pulmonary artery a long coiled thrombus might be found, blocking both main branches. If the thrombus was taken out carefully and disentangled it would be found that over the greater part of its length it was unbranched, but there were branches at the upper and lower ends, one end being paler than the other. If sections were made of the pale part the typical laminated structure characteristic of ante-mortem clot would be found. The upper end of the thrombus would appear rounded, and the other, the pale end obviously broken. From the length of the clot it might be assumed that it came from either of the two femoral veins. If those veins were now opened one of them might be found to contain a long eel-like thrombus and the other to be empty. Somewhere near the level of the knee would be found a broken end which corresponded with the broken end of the thrombus in the pulmonary artery. If further examination were made of the veins of the lower limb it would be found that the primary thrombus in a large proportion of cases arose in the muscular branches of the posterior tibial vein. When once organization had occurred the tendency to embolism would be enormously reduced, and there was evidence that organization occurred very rapidly, though it might not involve all portions of the thrombus at the same time. Thus a certain interval might elapse before the whole of the thrombus was organized on to the vein wall. Lesions in the media of affected veins were the result rather than the cause of thrombosis. He discussed the factors favouring embolism and said that the essential problem of thrombosis was why the platelets deposited where they did.

Dr HELEN PAYLING WRIGHT spoke of the modern experimental approach to the study of platelets. The precipitating cause of thrombosis was far from clear, but after operation there was an increase both in platelets and fibrinogen, reaching their maxima about the tenth day coincident with a slowing of the blood flow. Young platelets were more adhesive than older ones—a characteristic common to all young blood elements. She discussed the adhesiveness of platelets and gave an account of some experiments which suggested that adhesiveness was due to a surface film of fibrin.

Mode of Action of Anti-coagulants

Prof H P GILDING said this stickiness of the cells must somehow enable them to release the kinase and so initiate thrombosis. Dicoumarol as an anti coagulant would inhibit the formation of prothrombin in the liver, but such inhibition took time. A more rapid inhibition might be brought about by the injection of an adequate amount of heparin. With this substance it would take place within a period of seconds, depending on the circulation time from the vein into

which it was injected Heparin affected the stickiness of the platelets and tended to prevent them from agglutinating and perhaps from disintegrating Should one use vitamin K or a transfusion after excess anti coagulation therapy? For a quick reaction a transfusion of normal blood in adequate amount should be given, at the same time giving the patient vitamin K so that he could rapidly manufacture his own

Mr D H PATEY said that if a fatal thrombosis occurred it was commonly supposed that it was likely to happen on the tenth day after operation But it might occur on the first or second day, a surgical colleague of his had a fatal embolus in a patient on the way back from the theatre It was a question whether the static factor at operation might not have an effect, and it had been suggested that any increased incidence of thrombosis might be referable to the longer time taken over operations One impediment in the way of research and further knowledge was the fact that these occurrences were relatively so infrequent Hospitals were appointing resuscitation officers, and they might usefully be employed also as thrombosis or pulmonary embolus officers

Mr SOLLY COHEN said he had had a patient die on the table from pulmonary embolus It seemed particularly important that, before operation on a patient who had had a long rest in bed such as for gastric ulcer, the subject should be ambulant for at least a week Dr SHORT, replying to a question, said that a thrombus under 15 cm in length was not likely to cause sudden death, the thrombi which did produce sudden death were of 45-50 cm length So far as the effect of pressure was concerned it was a peculiar fact that it was not the more superficial of the calf muscles which were involved but the deeper soleus muscles

CARE OF CHRONIC SICK CONTRIBUTION OF PHYSICAL MEDICINE

At the meeting of the Section of Physical Medicine of the Royal Society of Medicine held on Dec 11 Dr F COOKSEY presided, and referred with great regret to the death of Dr A R Neligan, who was to have been one of the openers of the discussion, and whose paper would be read by Dr F I DAWSON

Dr E L STURDEE said that the problem of the chronic sick was becoming greater because of the larger number of old persons in the population In Great Britain in 1901 there were only 1,750,000 persons over the age of 65, in 1941 this number had increased to 4,300,000, and by 1951 it was estimated that it would have reached 5,000,000 An investigation in Surrey, however, had disclosed that 29.6% of the chronic sick in that county were under the age of 65 Owing to housing and economic conditions many of these people who would have been nursed at home were seeking admission to hospitals and occupying badly needed beds Public opinion—and medical opinion in particular—must be educated to the fact that the chronic sick constituted a problem with which it was not beyond medical knowledge to deal If every hospital took long-term patients medical students would realize the problem which would continually face them in private practice, and some at least would be interested enough to specialize All chronic patients could not be cured but they could be accommodated in annexes perhaps in the hospital grounds or at all events near the hospital and under its supervision Here they would be able to get about, though still needing medical oversight and could live in conditions more nearly resembling those of a private home Such annexes would not require nursing and domestic staff in the same proportion as the hospital proper The general public and especially the medical and nursing professions, must be made to realize that patients suffering from chronic illness had as much right to treatment as those with acute ailments

The paper by the late Dr A R NELIGAN detailed certain general and special methods of treatment

Dr MARJORY WARREN discussed clinical aspects of the chronic sick She emphasized the need for treating the patient as a whole—physically, psychologically and socially An atmosphere of optimism in rehabilitation was necessary Patients might become bedridden in various ways and some were confined to bed because of inadequate help for some minor lesion for example, an old man whose only trouble was stiffness in the hands and who was unable to dress himself Some old people were put to bed by indulgent relatives Other chronic

cases had been mismanaged and were suffering from loss of morale There were those who preferred to remain bedridden as the only way of avoiding a return to unsatisfactory social conditions

Treatment must be energetic and optimistic, and the patient must be inspired with confidence in his doctor It was important to keep patients moving in bed and as soon as possible to get them up even if only for a short time They should be encouraged to sit up to all meals and dress when able It should be explained that this was not for the convenience of the staff but because it gave better limb movements than any other form of exercise A hemiplegic should be given a full range of shoulder movements two or three times a day by the nursing staff, and if possible should be encouraged to do them on his own Occupational or diversional activities should be arranged as soon as possible Patients in the active stage of treatment should be separated from those in the earlier stages or the completely bedridden From the psychological point of view it was most important that the doctor should discuss the patient's condition with him It was necessary to keep in touch with relatives and friends When treatment was prescribed the doctor should see that it was carried out fully and he must obtain the co-operation of the nursing staff Adequate nursing staff was a first necessity, and when it was not possible to get enough trained nurses, nursing attendants were useful

CHILDBEARING SOCIAL AND ECONOMIC PROBLEMS

An inquiry into the maternity services of this country, and especially into the social and economic problems of the young mother, is being made under the auspices of a joint committee of the Royal College of Obstetricians and Gynaecologists and the Population Investigation Committee Two years ago a grant of £5,000 per annum for five years was made to the Population Investigation Committee for the purpose of research, and it was decided that an inquiry into maternity services would be most appropriate Dr J W B DOUGLAS was appointed research officer and at a meeting of the Eugenics Society on Dec 17 he gave an interim report

The inquiry has been aimed at discovering what use the mother made of the maternity services, the cost, including medical costs of her confinement, the regional differences between the services provided for mothers, the incidence of breast-feeding, and a number of other facts It was considered that the information could be obtained only by a direct approach to mothers all over the country, the interview was preferred to the questionnaire, and it was necessary that the interviewers should have a knowledge of maternity and child welfare Health visitors were the obvious people to undertake this task The co-operation of the Society of Medical Officers of Health and of individual local authorities was secured for a scheme whereby health visitors were requested to interview all mothers delivered during a single week in March last Out of 458 local authorities in Great Britain, 424 agreed to participate in the survey, the remainder were unable to do so owing to shortage of staff The field workers thus engaged were given a list of questions which had a very wide range, from such matters as antenatal care and the use of analgesia at the confinement down to the number of nappies in use for the baby and the cost of the perambulator The mothers were interviewed two weeks after delivery About 150,000 forms were completed, 2% of the mothers refused to co-operate and 8% could not be traced

The full report would not be ready until June, 1947 but some preliminary results were available Grouping the women according to the employment of their husbands a professional group accounted for 8%, black-coated workers 10%, and manual workers 65% In the professional group one birth in every twenty was that of a fourth or higher number child, in the black-coated group one in every ten, and in the manual group one in every four In the professional group those who were living in a population density of two or more for every bedroom and living-room—a high degree of overcrowding—numbered one in twenty, in the black-coated group one in ten and in the manual group one in four Considering the high proportion of wives of manual workers who had their babies at home this last was a shocking figure

Antenatal visits were almost universal, only 65 mothers had no care at all, and these were mostly mothers of illegitimate children who had concealed their pregnancies. On the average the professional group started to have antenatal care in the third month and the wage earners and manual workers in the fourth. The whole position with regard to antenatal care seemed to be most satisfactory. Most of the professional class went to their private doctors and most of the manual workers were taken care of by the local authority.

Care during the Confinement

It was in the care of delivery that the greatest differences showed themselves between the groups. The wives of men in the professional class received all round a higher standard of attention than did the wives of manual workers, and the wives of black-coated wage-earners came somewhere between. One out of every ten mothers in the professional group was delivered by a specialist, the corresponding figure for the wives of manual workers was one in fifty. Home delivery was much more common in the manual worker group. One in five of the women in the professional group was delivered at home, the figures for the other two groups were one in three and one in two, respectively. One in three of the professional group was delivered in a nursing home, but only one in seventeen of the wives of manual workers.

It might have been thought that in the same type of institution the members of the three social classes would receive the same quality of treatment, but this was not so. At home the mothers in the professional group were mostly attended by their own doctors, the wives of manual workers by midwives. Three out of five in the professional group who were delivered at home received analgesia, but only one out of five in the manual worker group. The same sort of difference obtained in institutions and hospitals. The proportion in the professional group who, being delivered in hospital, received analgesia was much greater than in the manual group. The black-coated wage earner group again occupying an intermediate position.

The same social distinction obtained in respect to the length of time spent in hospital. In the professional group the mothers stayed in the nursing home or hospital for an average of thirteen and a half days, the wives of black-coated workers for thirteen days, and those of manual workers for twelve and a half days. Behind these averages were hidden, for example the fact that those in the professional group rarely left hospital before the tenth day, whereas the wives of manual workers might have to leave hospital five days after the birth. These differences were not reflected in the averages.

The incidence of postnatal examinations the question being put eight weeks after delivery, was rather low in all the classes. Only four out of ten in the professional class and three out of ten in the manual worker class had had an examination by a doctor since the birth.

The figures were very consistent in showing how far the country was from achieving any equality of care of mothers as between different social groups. Such equality could not be obtained without a very considerable extension of existing services and the education of expectant and nursing mothers.

CHEMICAL MECHANISMS OF DEFENCE

Some of the chemical methods employed by the human body to rid itself of poisonous substances were described by Dr C R HARRINGTON, FRS of the National Institute for Medical Research when he delivered a Friday evening discourse at the Royal Institution on Dec 13, taking as his subject "The Body's Chemical Mechanisms of Defence".

Dealing first with substances of relatively simple composition he pointed out that, apart from excretion, oxidation was the simplest process used. Certain amines which, although toxic, might be produced in the intestine were easily oxidized (mostly in the liver) to the corresponding and relatively non-toxic acids. These might, either be excreted as such, or converted by conjugation with another compound into the excretory product.

One of the commonest and earliest recognized of conjugation reactions was the formation of the so called ethereal sulphates—sulphuric acid esters, production of which in small

amounts from food containing aromatic hydrocarbon groups was a normal physiological process. Benzene and other aromatic hydrocarbons if absorbed from outside, were dealt with in the same two stages—oxidation followed by conjugation to form an ester.

Aromatic hydroxy compounds he proceeded, as well as many hydroxy compounds in the aliphatic series, might also undergo conjugation to form glucuronides, which like the ethereal sulphates were readily excreted in the urine. The same process was also applicable to aromatic acids and acetylsalicylic acid while in some animal species the conversion of certain terpene alcohols such as borneol, into the corresponding glucuronide was so extensive as to form a reasonably convenient basis for the preparation of glucuronic acid.

As an example of the combination of aromatic and other carboxylic acids with nitrogenous compounds, Dr Harrington instanced the conjugation of benzoic acid with glycine to give hippuric acid. This reaction was common to many species and applied to many derivatives of benzoic acid in addition to providing the second stage in the detoxication of substances such as toluene which contained oxidizable side chains.

Species Differences

The detoxication of carboxylic acids showed species differences. Benzoic acid was conjugated with glycine in mammals but with ornithine in birds to form ornithuric acid, and phenyl acetic acid with glutamine in man and the chimpanzee, with ornithine in birds, and with glycine in the dog, cat, rabbit, and monkey.

With organic bases detoxication was by alterations in the basic group the commonest change being acetylation. This was the general reaction with aromatic amines, such as aniline and its derivatives including the sulphonamide drugs. Excretion was not however, necessarily facilitated, and the products of certain sulphonamides might be an embarrassment.

Chemically, one of the most interesting conjugations was that with acetylcysteine to form the so called mercapturic acids. This took place most characteristically with the monohalogenated benzenes and involved the direct linkage of the nuclear carbon atom of the benzene ring with the sulphur of the acetylcysteine. Because of this conjugation prolonged administration of bromo benzene might lead to cystine deficiency with delay of growth in young animals.

Antibodies and Allergy

The second and major part of the discourse was devoted to the antibody mechanism on which Dr Harrington has himself made important contributions. In contrast with the variety of defence processes invoked by relatively simple compounds there was here a single mechanism of extreme specificity. This was true of the response, not only to natural proteins, but also to proteins which had been artificially altered. Specificity in the latter case being determined by the new groups which had been introduced. Thus iodinated horse serum raised antibodies in the rabbit which were inactive against untreated horse serum protein but would react by precipitation with other proteins, including egg albumen, which had been iodinated. Similarly if sugar-protein complexes were prepared by the azo coupling method, familiar in dyestuff syntheses, the antibodies raised were determined by the nature of the sugar even small stereochemical differences being detectable. Finally Dr Harrington had himself been able to show that an antiserum prepared against a protein which had been combined with thyroxine could neutralize thyroid protein in which thyroxine was naturally combined. This was a physiological demonstration of the defence method against such a toxin.

Anaphylaxis and allergy appeared as an embarrassing variant of the same mechanism. A wartime example of sensitization was contact dermatitis from tetryl (2, 4, 6 trinitromethyl nitraminobenzene) an explosive which had to be made in large quantities. The experimental sensitization of guinea pigs, with tetryl and then with related substances had made it clear that the action depended on the formation after absorption through the skin of trinitrophenyl proteins which acted as antigens. The resulting antibodies which caused the skin lesions reacted to trinitroaniline compounds and to compounds which could form this group by combination with protein.

Correspondence

The Decision

SIR—What proportion of the profession can the individual doctor count on refusing to enter the new Health Service? The result of the plebiscite gives some sort of guide, but a much firmer guide is essential before the average doctor would risk refusing, whatever his opinions of the Health Service Act and however strong these may be.

Surely the only solution is for the doctors in every district to get together in small groups at the earliest possible date to discover what each individual is likely to do. He should not be asked, "Do you intend to enter the Service or not?" but the qualified question "If you were assured that a large majority of the profession is going to refuse to enter the Service would you?" The results of these meetings should be sent to B.M.A. Headquarters through the Divisions, and B.M.A. Headquarters should keep the groups informed at frequent intervals through the Divisions what returns are coming in from other districts.

It is only if we who individually object to the new Act know what the rest of the profession is going to do that we could contemplate refusing to enter the new Service on the appointed day. Discussions on the Act and alternative proposals for an amended Act are out of place at this stage—I am, etc.,

Sevenoaks

D E YARROW

The Need is Unity

SIR,—The *Journal* of Dec 21 makes inspiring reading. The profession whose attitude has been so strikingly demonstrated by the result of the plebiscite, may feel pride in its leadership. Its determination to resist bureaucracy and dictatorship has been clearly expressed. The battle is joined and we shall need to muster all our determination to carry it through.

The immediate economic prospect facing practitioners who follow the Council's lead and refuse service under the Act is a stern one. On the appointed day they will, of course, lose their insured patients while the unfortunately not inconsiderable disloyal minority will be in a position to secure large practices very quickly. Specialist appointments will also be affected by this position. This economic struggle will call for the greatest fortitude but it is better for the majority of the profession to see it clearly in good time. Under the leadership of Dr. Dain and the Council they will surely feel that the struggle is worth while if it leads to the overthrow of the Act. In the words of your leading article, the paramount need of the profession at this moment is indeed unity—I am, etc.,

London W9

A L JACOBS

The Plebiscite

SIR—Two of your correspondents reject my contention that the Labour Government has a clear mandate from the electorate to pass the Health Act on the grounds that the details of the Act were not published at the time of the election. Dr. A. K. Young (Dec 21, p. 960) goes further and writes that the great majority of the electorate are totally incapable of giving any intelligent mandate to anybody on their own account. That as may be. Political parties lay down the general lines of their policies and rightly claim a latitude in their execution. They could hardly do otherwise without infringing the right of Parliament to shape its own Acts. In the case of the Health Act the Labour Party had indicated its intentions in great detail in a pamphlet called *National Service for Health* which was published in 1943. The Act in no way conflicts with this announced statement of policy. No number of red herrings can alter this fact. In addition it should be noted that parties voting for the Act represent 15 million voters while those who voted against represent only 10 million. This is conclusive.

Dr. H. M. Stanley Turner (p. 961) claims that the Act is a purely political matter. Of course it is. The Labour Party is giving practical expression to its own political philosophy of which he happens to disapprove. I cannot agree with him that the 1944 plebiscite was a confusing document. Many

categorical questions were asked and answers given—e.g., a majority approved negative direction." A study of the results will prove my contention that the B.M.A. Council and the Negotiating Committee are out of line with the profession as a whole.

I accuse many opponents of the Act of being concerned primarily with their own interests and liberties and very little with those of the community. I accuse them of remaining silent during the years before the war when unemployment and starvation conditions were creating ill-health, and of rushing to print when their own standard of life is allegedly affected. I accuse the B.M.A. Council of adopting a narrow sectional viewpoint at a time of immense social change when it should be leading the profession towards the creation of a great health service—I am, etc.,

Bristol

H B O CARDEW

The Plebiscite and the S.R.M.

SIR—The Council is to move the following motion at a specially summoned Representative Meeting on Jan 28:

"That the Negotiating Committee be advised that in view of the results of the plebiscite the Minister be informed that, because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the Committee is unable to enter into discussions with the Minister on the Regulations to be made under the Act."

It has frequently been suggested that the decisions reached at Representative Meetings do not represent the views of the profession, and that persuasive oratory on the platform has played too important a part in its deliberations. At this crucial moment we should convince ourselves and the outside world that neither of these suggestions is correct by ensuring that our Divisional meetings are fully attended, and that our representatives are adequately briefed.

There is one further point which I should like to put forward for consideration. At the Divisional meetings which are to be specially summoned to discuss the Council's motion, each doctor should be handed a piece of paper upon which he will be asked at the end of the discussion to answer a plain "Yes" or "No" in favour of or against Council's motion. These slips should be handed to each doctor so that there will be no necessity for signatures and the secrecy of the individual doctor's vote will be obtained. The final voting figures should be announced by the Divisional chairman at the end of the meeting. If every Division in the country sent its representative to the Special Representative Meeting armed with these figures (and the total votes for and against should be publicly announced from the platform), I feel sure that they would reveal the fact that the profession is at last fully aware of the implications of the "Willesden affair" and what it may expect in the future.

I have written this letter with the approval of the chairman of my Division—I am, etc.,

R. PROSPER LISTON,
Representative Tunbridge Wells Division

Goodwill of Practices

SIR—I would draw attention to the eloquent letter of protest, as published in the Press sent to the Government by the representative bodies of the Insurance Companies and Investment Trusts in which they condemn the proposed unilateral method of affixing the purchase price of compulsorily acquired property. This is just what the Government is going to do to myself and the thousands of G.P.s who own their own practices. My practice represents my life's savings, and yet under the new Health Act I shall be compelled to sell out to the Government at their price which may or may not be a fair valuation—I am, etc.,

Witchaven

T S L JONES

National Health Service Act

SIR—Now the fight is on I think to begin with the B.M.A. should make an effort to give the public the true facts about this Health Act. The facts which I think are correct, are as follows. The late Government planned the Bill in the form of a White Paper which was handed to the profession for their

consideration and advice. Little alteration in this White Paper was considered necessary, and that little was agreed to by the Government but unfortunately before it could be made into a Bill the Government was out. As soon as Mr Aneurin Bevan was made Minister of Health our representatives approached him regarding the Bill, but were told he was too busy with housing to talk about health, despite the fact that the present Act was being prepared at that time. When we got to know this our representatives again approached the Minister with a view to negotiation and discussion but the Minister then said he was negotiating or discussing the Bill with no one.

Surely we, the persons who are mainly responsible for running the Service, should be the ones to know how it should be organized to the best advantage of the public. Mr Bevan has stated that the Bill has been passed and is the wish of the people of this country but I maintain that it is an Act made by Mr Bevan to nationalize medicine with no consideration for either the sick patient or the doctor.

I think it is time Mr Aneurin Bevan realized that when he was appointed Minister of Health he became a servant of the Crown and thereby of the people of this country, and cannot use dictator methods such as were used in Germany and Italy and which were the cause of the last war—I am, etc.,

Sutton in Ashfield

JOHN ANDERSON

SIR—The matter appears to me to be supremely simple. I am not interested in the details of furnishing, decoration or equipment of a house which I believe to be structurally faulty and dangerous, and which will apparently be the only house in which I shall be allowed to live. I have no desire to emulate the immortal Florrie Forde and be admired as a very useful bird in a finely gilded cage. Unless the builder is prepared to remedy its structural defects I am not interested in or tempted by details of its beauty or comfort—I am, etc.,

Rotherham

G H SEDGWICK

SIR—In the next week or two BMA Divisions will be called upon to discuss and instruct representatives whether or not to support the Council's resolution that the Negotiating Committee should not enter into discussion with the Minister concerning the regulations to be made under the Health Act. It is important for each one of us to realize what exactly this implies and to consider whether or not it circumvents the already declared view of the majority of the profession as expressed in the BMA referendum of 1944.

The issue, as recently restated by the Chairman of Council at Exeter is: Does the Act sufficiently conform with the principles of the profession to permit further negotiation with the Minister? What are these principles? Close examination shows them to be no more than a thinly disguised stratagem to have excluded from the Act the prohibition of the buying and selling of practices, payment partly by basic salary partly by capitation fee and what is misrepresented as direction of the doctors. There is not the slightest doubt that the enabling Bill demanded by Dr Dain in the same speech would have for its purpose the exclusion of these particular clauses. With regard to these three issues the 1944 plebiscite showed the Council of the Association to be quite out of touch with the opinion of the profession as a whole and this was particularly evident in the case of the younger doctors represented by the Forces. It is greatly significant that the present plebiscite reveals this tendency still to exist as doctors with 14 years experience and under show a majority in favour of negotiation.

It would be difficult to deny that the Council has consistently ignored the results of the 1944 questionnaire and, far from democratically accepting the majority point of view on these important issues has by a persistent and often emotional propaganda campaign endeavoured to impose its own view on the profession. To that end in the present plebiscite, with the voting forms were issued a statement condemning the Act and a letter from the Secretary which was not likely to impress the doctor in its favour. There was at the same time published in the *Journal* the speech by Chairman of Council at Exeter, in which he practically advised the doctors to say 'No'.

In spite of all these manoeuvres a majority of less than 8% of the profession actually voted 'No'. This can hardly be

regarded as the 'substantial majority' laid down by the last Representative Meeting. In the forthcoming Divisional meetings the issue which has really to be decided is whether or not the present Council or the profession as a whole is finally to determine policy. It is not without significance in this respect that the proposer in Council of the resolution presently before the doctors is that same member of Council who, in 1944, before the Act was even conceived, resisted the election of the present Negotiating Committee for the purpose of consulting with the Minister concerning the future health services of the country—I am, etc.,

Edinburgh

S LIPETZ

The BMA and Public Relations

SIR—As the issue has now been joined with the Ministry of Health over the new Health Service I wish to suggest that every attention be given to the publicity side of the campaign. It is always said that however popular individual doctors may be the medical profession as a whole has had a bad Press. It is absolutely vital that the public should appreciate the various points in the new Act which we consider are so unsatisfactory to them and to us. Public meetings should be called in the big towns to ventilate the questions and inform public opinion. It would be a great help if medical men were furnished with a concise tabulated statement giving them the salient points in the matter and the vital principles involved, to convince the waverers and to provide the whole profession with the necessary ammunition. The many channels of advertising should all be employed. There can be no better use of the fighting fund than to devote a portion of it to securing more public support without which there is little prospect of real success—I am, etc.

St Leonards-on Sea

W GOVER

The Unstable Adolescent Girl

SIR—The appendix to the Report of the Committee on Psychiatry and the Law published in the *Journal* of Dec 14 (p 909) and the leading article in the same issue (p 904) draw attention to an urgent social problem. While agreeing with the writer of the leader that "doctors and magistrates alike have approached their problem in a realistic and scientific spirit" it seems unfortunate that the appendix as published should contain a number of misleading statements. Take for example, the sentence "In many ways girls of higher intelligence are more dangerous to the community than girls of a lower intellectual capacity" (paragraph 34), or, "if it [the IQ] is above 70 they are apt not to be regarded as mental deficiency cases because of a misinterpretation of the Mental Deficiency Acts" (paragraph 10). No statement is forthcoming however, to explain which cases may be dealt with under these Acts.

In the first paragraph the committee describe a particular type of girl with whom they are concerned, yet in the ensuing paragraphs deal with mentally defective, morally defective socially defective psychopathic, and—in that some are expected to respond to psychiatric treatment—psychoneurotic cases, as though they presented a single problem.

Clinical observation and detailed study of the unstable adolescent girl have shown the importance of basing diagnosis upon both mental capacity and social maturity and of giving due consideration to the home circumstances before arriving at a recommendation. If a girl's intelligence quotient is below 70 the degree of incomplete development of mind is such as to warrant her being regarded as simple minded. Whether she will require to be dealt with under the Mental Deficiency Acts will depend upon the extent to which she is also socially defective and the ability or otherwise of her parents or guardians to exercise the necessary care or control for her protection. If a girl's intelligence quotient is between 70 and 90 she should be regarded as being intellectually dull. In an exceptionally good home environment she may respond to supervision while on probation. If she shows strongly vicious or criminal propensities she can be dealt with under the Mental Deficiency Acts as being a "moral defective" but cannot strictly be dealt with as being "a feeble-minded person" if the intelligence quotient is more than two or three degrees above 70. The majority of girls in the dull group will require a period of from two to three years in a residential school or training

centre. Some will respond satisfactorily to this lengthy period of discipline and character building, for others the provision will prove to have been purely preventive. In relatively few of the cases in which the intelligence quotient is below 90 will there be any permanent response to psychiatric treatment. In those cases in which the intelligence quotient is 90 or more (and I Qs as high as 140 will be encountered among those who are persistently delinquent) the primary need is to determine the level of social maturity. In the absence as yet of a social maturity scale of general applicability the most reliable guide is a study of the girl's personal history from infancy onwards. Precocious physical and emotional development is a common feature in the history of the more intelligent girl, and absence of understanding, help, and advice on the part of parents or teachers a contributory factor. It is this group of cases that provides the most favourable material for psychiatric investigation and treatment.

When the committee have obviously gone to much trouble to collect and sift facts relating to the problem of the unstable adolescent girl it seems unfortunate that the above general principles upon which recommendations must be based have not been more clearly enunciated—I am, etc.

Liverpool

MURIEL BARTON HALL

Migraine and the Sympathetic Nervous Pathways

SIR—Mr G F Rowbotham's article (Sept 7 p 319) on 'Migraine and the Sympathetic Nervous Pathways' has just come to my notice. Several points seem worthy of comment. It is noted that Case IV did not respond satisfactorily to surgery. This it is felt could have been avoided by not subjecting him to the operation. The procedure we have adopted should obviate surgery on cases unlikely to respond.

I have personal experience of three cases of migraine which we have cured by cervical sympathectomy. In the first case stellate ganglionectomy was performed on account of status anginosus, and it was noticed that a left-sided migraine which had been present for years was abolished. The second case was that of a woman of rather neurotic tendencies who complained of a unilateral migrainous type of headache. In view of the possibility of a psychogenic origin it was decided to determine before embarking on any surgical procedure whether it was likely to improve her condition. Mr Trumble first of all injected the region of her cervical sympathetic with normal saline, with no effect on her headache. He then substituted 'novocain,' and with the appearance of a Horner's syndrome the headache was abolished. The cervical sympathetic chain was then divided under local anaesthesia, and on stimulating the cut end of the latter the patient complained of having her 'headache.' Following operation she has remained well and has had no sign of any recurrence of symptoms over a period of nearly two years.

In the third case the patient complained of typical unilateral migraine of many years' duration. During an attack I injected her cervical sympathetic with 'novocain,' and with the appearance of a Horner's syndrome the migraine was abolished. Mr Grayton-Brown performed a cervical sympathectomy, but could not reproduce her migraine by stimulating the cut end of the sympathetic chain. She has so far remained well and free from any untoward symptoms.

Three other cases in which operation might easily have been undertaken were found not only to be unrelieved by local anaesthesia of the cervical sympathetic but were made worse by it. Thus three failures were avoided. I would like to suggest to Mr Rowbotham that he adopt the simple procedure of infiltrating the cervical sympathetic with 'novocain' prior to operation so that cases suitable for this form of treatment can be selected. The ligation of the external carotid does not seem to be necessary and was not carried out in any of our cases—I am, etc.,

Melbourne

S A SEWELL

Mental Deficiency

SIR—I wish to draw your attention to what appears to be an inaccuracy in Any Questions under the heading 'Mental Deficiency' (Dec 14 p 929) where there appears the statement, 'The sole criterion is what is best in the interests of the child.' Although that may have been the standard until recently, the

Education Act of 1944 gives to local education authorities the power to order special educational treatment for mentally deficient children not only in their own interests but also in the interests of the other children in the school which they would normally attend. The relevant section is 57 (4), which states

For the purposes of this section, a child shall be deemed to be suffering from a disability of mind of such a nature and extent as to make him incapable of receiving education at school not only if the nature and extent of his disability are such as to make him incapable of receiving education, but also if they are such as to make it inexpedient that he should be educated in association with other children either in his own interests or in theirs.

I think you will agree that although the ten-year old mongolian idiot may be quite happy in the village school, the local education authority would be justified in removing the child in the interests of the other pupils—I am, etc.,

Leeds

MARY N M PAULIN

Use of Penicillin Pastilles

SIR—Dr G C Pether's letter (Dec 14, p 920) on the possible dangers of oral penicillin may indicate a rather wide interest in this matter and one or two further points may be made. The correspondence, to which a number of the readers of this *Journal* have contributed, arose from a Question and Answer in the issue of Sept 21 (p 447). Your technical expert there stated that stomatitis after oral penicillin was rare, only four cases having been reported. In subsequent issues there have been a number of letters reporting further cases, and the impression is growing that commercial penicillin pastilles supplied for the local treatment of sensitive oral infections may be quite a frequent cause of sore tongue and sore mouth. The matter seemed to be clinched by the communication of Drs Ellinger and Shattock, 'Nicotinamide Deficiency after Oral Administration of Penicillin,' in the issue of Oct 26 (p 611). The authors demonstrated that a clinical picture of nicotinamide deficiency, associated with a diminution of nicotinamide methochloride output, might follow the oral ingestion of a few thousand units of penicillin daily for several days in a subject who was apparently rather sensitive to dietary nicotinamide deficiency. These workers concluded that the penicillin swallowed by their subject had inhibited the metabolism of intestinal flora and diminished the quantity of the vitamin usually available from this source.

That, this may not be the whole story of 'penicillin stomatitis' is suggested by the following two considerations. (1) Whether in the ordinary way penicillin derived from sucking pastilles would be likely to reach the colon in sufficient quantity. (There is evidence that little penicillin enters the intestine from the blood-stream—e.g., McDermott *et al* (1946)—and so we may take it that the drug must reach the colon via the small intestine.) Supposing a 500 unit pastille is dissolved in the mouth in fifteen minutes, 2,000 units an hour are slowly swallowed or absorbed from the buccal membranes. Of that portion which reaches the small intestine a further fraction will be absorbed (Abraham *et al*, 1941, Florey and Florey, 1943). This appears to occur mainly from the duodenum (McDermott *et al loc cit*). This small dose would probably be insufficient to give demonstrable blood levels, from the evidence of Burk, Ross, and Strauss (1945), McDermott *et al* (1945), Krantz, Evans, and McAlpine (1945), the evidence assembled in a recent editorial in the *Lancet* and other work.

The recent work of McDermott and his colleagues (*loc cit* 1946), quoted by Ellinger and Shattock, emphasizes the irregularity with which ingested penicillin is absorbed from or retained in the small intestine. Of two subjects who had received oral penicillin in a single dose of 5 million units, apparently in aqueous solution, the stools of one were found to contain 0.94 units of penicillin per gramme of stool, and of the other 1.200 units per gramme. In another subject, who took 100,000 units orally in water at two hourly intervals for a twenty-four-hour period, the stool (held till the end of the experiment) contained no demonstrable penicillin. It is clear that the doses with which these authors worked far exceed the quantity one would swallow from sucking pastilles through a day, where ten or twenty probably represent as many as most patients would take.

(2) Whether the triad of sore tongue, sore mouth, and sores at the angles of the lips, which may be due to vitamin deficiency, could receive another explanation in these particular circumstances. Unfortunately most of the clinical work on oral penicillin has been limited to gonorrhoea, where the total dose is usually given inside of one day, but in this connexion it is perhaps worth noticing that in the very careful paper by Bushby and Harkness (1946), a subsection, "Toxic Manifestations," does not mention this particular complication. Florey and Florey (1943) treated a case of right orbital cellulitis with 60,000 units daily for seven days by capsules and duodenal tube, and a case of sensitive actinomycosis with 80,000 units daily for six days by duodenal tube, and do not mention that either case developed stomatitis or glossitis, although the second case (whose primary disease was unrelieved) developed coryza and gastro-intestinal disturbance.

It seems to me that Dr T V Cooper is on the right lines when he suggests that the commercial lozenge base may be at fault. Until we have work of the quality of that of Ellinger and Shattock supplemented by readings of penicillin blood levels, gut levels from a Miller-Abbott intestinal tube (with its tip positioned by contrast fluoroscopy to be in the region of the ileo-caecal valve), and perhaps by urinary and stool penicillin levels, and by stool culture, I feel we may continue to use oral penicillin for oral infections, but that we should order lozenges made with agar or gelatin (as has Dr Cooper) until it has been shown that the base alone and the heat-inactivated pastilles are not the cause of the stomatitis—I am, etc.

Epidemic Gastro-enteritis

SIR—Having heard on the wireless and read in the newspapers about the outbreak of an epidemic of gastro enteritis among maternity patients and newborn babies, I would like to mention how similar cases have been treated successfully by myself both abroad and here in Dorking County Hospital. It is the treatment which was used in the Berlin City Orphanage by Prof Finkelstein and L F Mayer.

The aim of the treatment is to prevent dehydration and make the patient afebrile. It starts with a short period of starvation, during which only weak cold tea sweetened with saccharin is given. (1) 1 dr (3.5 ml) is given every 5 minutes until vomiting has ceased for about 1–2 hours. (2) Tea is gradually increased (cold or warm) for no longer than another 8–12 hours. (3) Expressed breast milk is then given—12 g 2-hourly for 24 hours, and increased daily by 10 g until the 5th or 6th day. (4) 3-hourly feeds are then given, the amount required according to age and body weight.

As the mothers are ill also, I would advise sterilizing the expressed breast milk. If breast milk is not available buttermilk may be used. Unfortunately reliable brands of buttermilk are not always available, but it can be obtained by using the milk left over from making butter from sweet cream. This milk should be boiled with 1% flour and 3% sugar—I am, etc.

Cerebral Malaria in Great Britain

SIR—Drs J B Ryder and R T Towson (Nov 30, p 815) state that in the literature they have only found two cases of cerebral malaria in Great Britain recorded. In the *British Medical Journal* 1930, 1, 336, I reported the case of a gentleman aged 35 who had just returned from West Africa. He had a rigor for which he took 10 gr (0.65 g) of quinine. Instead of being better the next day he had a very severe head-

ache, and his temperature was still up. He called in a doctor who prescribed more quinine without effect. The headache became worse and worse, and vomiting set in. That night he was very delirious, with intense headache and frequent vomiting. Morphine gave him no relief. In the morning I was asked to see him as a case of meningitis. He was then semi-conscious, with a temperature of 103.6 F (39.8 C), pulse 112. His head was retracted and could not be moved forward. There was double Kernig's sign, and the toe reflexes were extensor. The abdomen was retracted, the spleen could just be felt below the ribs, and the liver was slightly enlarged. Some of the vomit during the night had been of coffee grounds character.

I came to the conclusion that the case was probably one of cerebral malaria, and had 10 gr of quinine hydrobromate injected into the buttock, and another 10 gr into the other buttock in two hours, and another injection in four hours. Soon after this the patient became perfectly conscious and free from headache and vomiting. He was given an intramuscular injection of 10 gr twice a day for the next three days, and had then quite recovered. This case illustrated the fact that quinine by the mouth is no good in cerebral malaria.

Since then I have seen post mortem a child of 2 who had returned from India, where she had had malaria. She was taken ill one morning about 8.30 with headache, had a rigor with a temperature of 104° F (40° C) and became comatose at midday, she died at 4 in the afternoon. Malarial parasites were found in the blood after death—I am, etc.

WALTER BROADBENT

Dental Anaesthesia after Coronary Thrombosis

SIR—Like Dr F Barnett Mallinson (Dec 14, p 921), and I am sure many others, I could not agree with your correspondent that a person recovering from a coronary thrombosis was a normal anaesthetic risk. Dr Mallinson has suggested treatment which should ensure the patient against any mishap or untoward occurrence, and I doubt if safer treatment could be suggested. However, I venture to point out that it is most unlikely that a hospital patient would be afforded the opportunity to have teeth extracted a few at a time in this way, and so a different regime must be laid down as a routine treatment of a not uncommon condition.

The requirements during this anaesthetic are that the patient should be well oxygenated at all times, that the anaesthetic should be smooth, and of course that the required plane of anaesthesia should be reached but not passed. In your issue of June 17, 1945, I mentioned a technique that I had used considerably on very bad risk cases with complete success. This is quite applicable to out-patient dentistry and, I consider very suitable for the case in point. No sedative premedication is given, though atropine sulphate 1/100 gr (0.65 mg) is probably indicated. With the patient in the dental chair a syringe of 5% 'pentothal' (thiopentone) is strapped to the arm after the needle has been introduced into a vein. Before any 'pentothal' is given the nose-piece of a gas and oxygen apparatus is applied to the face while 100% oxygen is run through the machine. Only when the patient is breathing this smoothly is the 'pentothal' run in. This is given slowly speed depending on the severity of the risk, but the respiration must not be allowed to get shallow, and so the patient will remain a good colour. When unconsciousness has supervened the gaseous mixture is altered so that the oxygen percentage is reduced and replaced by nitrous oxide. With a bad risk this must not go below 50% at first, and some lose their full pink colour at this stage. Others, such as the convalescent coronary case, will rapidly tolerate 25% or 20% oxygen. Further injections of 'pentothal' or alteration of the gaseous mixture are made as and when required but it must be realized that it is better to give more 'pentothal' than to cause any degree of cyanosis. With out-patients the minimum of 'pentothal' will be given, and so the maximum use will be made of the nitrous oxide, consistent with the patient remaining a good colour. With in-patients this is less important but it must be remembered that as a group they are a different type of case. In this way a few dental extractions can be made after only 3–5 ml of pentothal.

Speed during the preliminary stages of the anaesthetic should not be aimed at. The safety of the patient is the only thing

'Benadryl'

An Anti-allergic and Anti-spasmodic Agent for Oral Use

'Benadryl' (β -dimethylaminoethyl benzhydrol ether hydrochloride) is a synthetic compound which belongs to a new and distinct pharmacological group having a specific anti-histamine action.

Extensive clinical studies have shown that 'Benadryl' affords relief in a variety of allergic manifestations, including hayfever, urticaria, contact dermatitis and serum reactions. It is also effective in relieving the spasm of smooth muscle, such as may occur in dysmenorrhoea, etc. 'Benadryl' is administered orally and, in responsive conditions, it exerts a beneficial effect within a few hours. The most striking results reported have been in the control of symptoms associated with hayfever and urticaria.

Benadryl' is issued in bottles of 50 capsules each containing 50 mgm

A booklet describing 'Benadryl' will be sent on request

GOLD THERAPY

GOLD therapy now takes a foremost place in the treatment of rheumatoid arthritis. Toxicity, formerly of sufficient severity to detract from its general usage, has been materially reduced by a more careful selection and management of cases and much lower scale of dosage, and the development of less toxic gold salts. Crookes' Auro-Calcium, a finely divided aqueous suspension of calcium aurothiomalate, provides an appreciable contribution to this reduction of toxic effects.

Crookes

AURO-CALCIUM

Available in single ampoules and in boxes of six ampoules
Strengths 10 mg, 25 mg, 50 mg, 100 mg

THE CROOKES LABORATORIES LIMITED
PARK ROYAL LONDON, N W 10

CALCIUM-SANDOZ

- * The calcium is present in the form of calcium glucono-galacto-gluconate. This solution is perfectly stable without the addition of foreign substances.
- * Available in two strengths, corresponding to 10% and 20% calcium gluconate.
- * The 10% ampoules may be given with safety intramuscularly, without pain or irritation to the tissues, or intravenously with the minimum of reaction.
- * The 20% ampoules are best reserved for intensive therapy by the intravenous route.

that matters, and speed may well lessen this. Once they have reached the stage of surgical anaesthesia by this gradual process, very gravely ill patients will stand a prolonged anaesthetic very well provided there is no need to take them into the deeper planes. Frequently I have seen their blood pressure rise appreciably during 60 to 90 minutes of such anaesthesia.

This regime requires no special skill and no special apparatus—it can even be done with foot cylinders providing oxygen is used. There is no need for an operating theatre or to admit the patient and so I feel that it should be mentioned in the treatment of this and similar cases. I have used this technique now on so many bad risk cases, especially during the war that I feel that anyone who is not on the point of death can be taken to the first plane of the third stage with safety and when I heard a few days ago at the anaesthetic section of the RSM of a grave risk case that did not survive a 1 ml dose of "pentothal" I came away feeling that had oxygen been given first the result might well have been different—I am, etc.

Postgraduate Education

SIR—I was pleased to read the letter of Dr J Maclean Smith (Dec 14, p 921) in which he pays tribute both to the warm welcome which was extended to the medical officers of the British Pacific Fleet by our colleagues in Australia and to the postgraduate educational opportunities provided out there. I have no doubt that there are many others who like Dr Smith, are grateful for having had experience of such postgraduate instruction. While in Australia as surgical consultant to the BPF I was invited to become a member of the Postgraduate Committee on Medical Education of the University of Sydney and was able to attend a number of meetings at which the excellent work being done for postgraduate education by this committee became very apparent to me.

The correspondence tuition to which Dr Smith refers was conducted by senior members of the teaching staff who devoted much care and attention to it and was supplied to medical officers away on service stations such as New Guinea and the Pacific Islands. It was much appreciated and is an idea which might well be given consideration here. Many medical officers from this country on far-away stations have adequate enthusiasm and much time on their hands and would no doubt welcome something like the Sydney correspondence courses. In Melbourne and Sydney, and indeed throughout Australia and New Zealand, postgraduate medical education has reached a high standard of efficiency. I should like to take this opportunity of again expressing thanks to our colleagues in Australia and New Zealand for all their kindness to those of us, who were out there with the Fleet, and in joining with Dr Smith in hoping that friendly postgraduate teaching within the British Commonwealth will long continue and progress—I am, etc.,

Cardiff

LAMBERT ROGERS

Venereal Disease Control

SIR—I read with rising alarm the article (Nov 30, p 825) by Lieut-Col R R Willcox on 'Some American Ideas on Venereal Disease Control'. I could not help feeling that this eminent venereologist viewed these American methods favourably, and was without saying so explicitly seeking to further them in this country. As a medical officer of health I am naturally anxious to secure that transmissible diseases are kept under control by all reasonable methods but I think that there is a general tendency at the present time to lose sight of wider ethical considerations in trying to achieve immediate administrative results. Interference with the liberty of the subject can scarcely be too much curtailed and the idea of compulsory investigation for venereal disease before marriage cannot, I think, be too strongly deprecated.

Even the risk that a relatively small number of people may infect others with a dangerous complaint should not be allowed to stampede us into further restrictions upon civil liberty, particularly at a time when the profession as a whole is trying to maintain its freedom against those who desire to enslave us, for the sake of perfectly laudable immediate results—I am, etc.

Weston-super-Mare

CYRIL G EASTWOOD

Errors in Diagnosis

SIR—During the last six months I have had no fewer than four cases in which diagnosis of anxiety neurosis and nervous dyspepsia had been made, and which turned out to be (1) gastric ulcer, (2) carcinoma of stomach, (3) carcinoma of stomach, (4) advanced pulmonary tuberculosis. All these cases had been attending hospitals over a period of some years.

My contention in writing this letter is that too much attention seems to be paid to patients' neurotic symptoms rather than to seeking some organic cause. The diagnosis of nervous dyspepsia or anxiety neurosis is too easily made. Further investigation—x-ray examination—should, I feel, be made in all cases complaining of dyspepsia to exclude new growth. I have for some years now made it a rule that any patient complaining of dyspepsia for more than four weeks should go to hospital for x-ray investigation—I am, etc.,

Willesden

L SHELDON

Treatment of Ingrowing Toenail

SIR—I was rather surprised to see in the *Journal* of Oct 19 (p 589) Lieut-Col J C Leedham Green's letter recommending as a simple and most satisfactory procedure that old-fashioned method of paring the nail with a piece of glass. Anyone who will try it will agree that it is a most tedious and unsatisfactory procedure. Years ago (in 1914) an American surgeon described a new method which is so simple that any doctor can easily do it under local anaesthesia, and the result is excellent and permanent. He pointed out that "ingrowing" is a misnomer, as the nail does not start growing sideways. What happens is that the toe irritated by the pressure of the shoe against the edge of the nail gets bigger, as anyone can see, so that often the nail gets partly embedded in the toe.

The logical thing to do is at the same time the simplest and best. A good wedge should be cut out of the side of the toe cutting right down to the bone. The inflamed edge near the nail is left severely alone but not so much should be cut out that the edges of the wound cannot be brought together without tension. A little 1% 'novocain' is all that is required for anaesthesia. Two or three stitches and a gentle pressure bandage complete the simple operation. Sufficient tissue should be cut away that the nail may again rest comfortably on top of the nail bed instead of seeming to grow into it. A few days in bed is advisable for rapid healing.

The relief is wonderful and the result as a rule permanent if the operation has been performed *lege artis* but if not enough flesh has been removed it is quite easy to remove some more at a second sitting and sometimes the inside may be treated as well in the same way till a nice small toe is obtained protected by the nail as intended by nature. It is really surprising that this operation is not yet being universally taught, as it is so logical, simple and effective—I am, etc.,

Rustenburg Transvaal

S J D ESSER

Advertising Patent Medicines

SIR—In the *Journal* of Dec 7 (*Supplement* p 150) the report of a debate by the Hunterian Society quoted one doctor as stating that £90 million a year was spent on the advertising of "patent medicines". In the recently published report, *Statistics of Advertising* which was based upon inquiries carried out by the National Institute of Economic and Social Research on the initiative of this Association, the figure of expenditure by manufacturers on the advertising of patent and proprietary medicines, tonic wines and rupture appliances in 1935 was £4822 000, almost exactly the figure which Mr Mortimer quoted for 1938 in respect of the Press only. The Institute's computation however comprises Press, outdoor, and radio advertising and represents 74% of total advertising expenditure directed to the final consumer in that year. It should be noted moreover that the medicines, etc., the advertising of which represented £48 millions excluded all products where the ratio of advertising cost to sales was under 3%. In computing these figures the Institute has indicated the possibility of considerable margins of error, of the order of 10% to 20%.

The Advertising Association is now planning to collect systematic statistics *inter alia* in relation to proprietary advertising. One object will be to eliminate the considerable margin

of error which may exist in the figures for particular categories, such as patent medicines and toilet preparations. The statistical investigation recently concluded provides a most useful starting point to a continuous statistical system. Meanwhile, deductions from the present figures should be drawn with caution. It would be fair to add that the fact of a proportion of advertising expenditure of 25% or more in relation to sales is by itself no measure of the relative merits or demerits of the preparations advertised. The great bulk of this type of advertising is subject to a considerable measure of supervision in one way or another, but the Association and its affiliated bodies recognize that the existing standards of restraint require to be made more explicit, more concise, and more uniform. We believe we are making progress to that end with the general support of professional bodies, such as the British Medical Association, who have been consulted—I am, etc.,

J L HENDERSON

London EC4

Director and General Secretary
Advertising Association

Amenorrhoea during Internment

SIR—I have just read Dr Anne Sydenham's article (Aug 3 p 159) on 'Amenorrhoea at Stanley Camp, Hongkong, during Internment'. It is interesting to recall a somewhat similar condition when the Japanese first occupied Ipoh, seven weeks before the fall of Singapore. In spite of the chaos I was able to see about 30 cases of amenorrhoea, especially among young unmarried girls. There were then numerous cases of rape and conditions were most uncertain. Food however, was not so very difficult to get owing to stocks left over by the British. Nearly all the cases started menstruating again without any treatment after 4-5 months, when conditions were slightly more settled. I would put the cause of all these cases to emotional shock—I am, etc.,

Ipoh

GOH TEIK WAH

Pay of Pathologists and Bacteriologists

SIR—I very much regret that my letter provoked the thought that I consider a specialist to be of higher prestige than the GP—at least this would appear to be the case on reading Dr G Behr's letter (Dec 14, p 919). Having been a GP myself I can assure Dr Behr that in my opinion there is no higher prestige than that of the family practitioner's which, however, does not alter my contention that the present salaries paid to pathologists and bacteriologists are little short of outrageous.

If a GP earns, say, £1,500 per year (and a doctor is capable of doing so within a year or two of qualification) then the pathological specialist should be paid accordingly—i.e., a similar sum. I do not think this unreasonably 'rebellious'. I hold no brief for a salaried medical service, but sometimes I wonder if such a service is the only means by which the "junior" pathologist will be freed from a most unjust system of remuneration—I am, etc.,

LABORATORY DOCTOR

Diet and Canine Hysteria

SIR—Allow me to congratulate you on the publication of Sir Edward Mellanby's article (Dec 14 p 885) and your excellent leading article thereon (p 903). For some years now the veterinary profession have realized the importance of a toxic substance or toxic combination in diet as being a direct and positive cause of specific hysteria, so called 'Fright's disease' or 'running fits' and Sir Edward's contribution has gone a long way to narrowing down the possible causes. As you indicate the next step is to study the result of feeding agenzized wheat gluten to dogs and if this fails to produce the disease, then to study the effect of the agene process on all or part of the vitamin B complex.

M B Richards, in the *British Medical Journal* (1945 1, 433) describes a pyridoxine deficiency in suckling rats whose dams had received a high aneurine content. In *Nature* (1946 158 306) she records that in the experiment described above she observed but did not report that fits were not manifested in litters where dams received national wheatmeal flour 85% extrac-

tion instead of white flour. I understand that in this part of the country during the war it has not been normal practice to apply the agene or any bleaching or improving process to flours of high extraction rate, and it is possible that Mellanby's work would throw fresh light on Richards's experiment.

By the same token the next interesting step would be to feed pyridoxine with diets known to be capable of producing hysteria, and if this prevents the disease the problem will be further elucidated. The veterinary profession has known for a long time that certain batches of dog food are capable of producing hysteria, and I have access at the moment to a bag of dog food which will produce hysteria in less than a week from the time feeding is commenced. I have had some pyridoxine on order for some months which I hope to receive shortly, and propose using it as a therapeutic on dogs fed on a known hysteria producing diet. Mellanby's article indicated that rats were not affected but it may well be that the hysteria syndrome is only manifested in adult rats when the toxic factor is present in large quantities, and small quantities can only be demonstrated in suckling rats whose dams have been fed on a hysteria producing diet.

With regard to the human aspect of the problem I do not think the new facts necessarily present a grave problem, as there is no doubt that pre-war experience demonstrated that the toxic factor was much greater in dog biscuits than in bread—even white bread—as evidenced by observation of kennels of dogs fed on both these diets. On the contrary I have frequently seen hysteria developing in kennels where ship's biscuits (emergency lifeboat rations) were fed and I have very infrequently seen hysteria follow feeding with 'brown bread'. Any complete set of experiments would require to take into account the high temperatures associated with baking.

Sir Edward's description of the fits is excellent, and it is a matter of some importance that in specific hysteria the dog's nervous condition is not normal between fits. I would like to issue a word of warning here. In the past, as indicated in the article a multiplicity of causes were implicated as being responsible for hysteria and this was not without some reason. Conceding that specific hysteria occurs as described and is caused by a toxic factor in food it must be recognized that hysterical attacks clinically indistinguishable from those described do occur due to the virus of distemper in dogs that have had no hysteria producing foods. In the past two years outbreaks of distemper of a very virulent type have frequently been ushered in by typical hysteria to be followed later by the more common distemper symptoms. It may be that the virus creates a set of circumstances whereby larger quantities of an accessory food factor are required than is normal analogous to the increased demand for biotin in rats given avidin.

Another interesting feature whereby a virus appears to have an antivitamin effect occurs in distemper in puppies between the ages of 2 and 4 months. Such animals develop the condition described by May Mellanby as dental hypoplasia even while large quantities of vitamin D are given during the disease. Mellanby produced this condition in the disease free puppies by diets deficient in D and it might be that in distemper there is a failure to assimilate D because of associated bowel catarrh. Or again it may be that the requirements are greatly increased by the action of the pathogenic agent. I have tried the effect of radiation by ultra-violet light in such cases but in practice there are difficulties in carrying this out and results have been inconclusive. The question could be readily solved by the experimental method. An investigation of such altered vitamin requirements would probably indicate the way to their more rational therapeutic use—I am, etc.,

Glasgow

WM L WEIPERS

Dr George Gunn, MBE FRCS, of Crowborough, Sussex who died on April 3, 1946 left £10,189. Dr W S A Griffith, CBE FRCP, FRCS, of Haslemere, Surrey, who died on Feb 26, 1946 left £79,989. After various legacies he bequeathed one third of the remainder to St Bartholomew's Hospital for the development of the obstetrical and gynaecological department to perpetuate the name of Dr Matthews Duncan and one third to the medical college. Dr Howard Henry MC MD, of Debenham Suffolk who died on June 24, 1946 left £14,564. Dr A B Murray of Birnfi who died on Oct 13, 1946, left personal estate in England and Scotland valued at £45,850.

Obituary

Dr DORIS MARY RINGROSE died at West Park, Leeds, on Nov 7 at the age of 46. She was educated at George Watson's Ladies College, Edinburgh and graduated M.B. Ch.B. at Edinburgh University in 1923 taking the D.P.H. the following year. She worked in general practice until 1926, when she settled in Leeds and married Mr H. T. Ringrose, the pioneer of automatic firedamp alarms in mines. The principle of this device has recently been applied to the continuous indication of anaesthetic vapour concentrations. In 1930 Dr Ringrose resumed her medical work and until her illness was employed by the West Riding County Council and the Batley Corporation on antenatal and child welfare work. During the war she served on a medical board for recruitment to the women's Services. She also took a great interest in industrial medicine. She was a woman of truly high ideals, of great kindness of heart, and she was a very loyal friend. Her death came as a great shock to all those who knew her and she will be greatly missed. *She leaves a daughter who is still at school and a son now studying medicine at Cambridge.*—H. F. H.

Dr GEORGE LOCKE, of Hastings, died in retirement at Sedlescombe, on Nov 19, at the age of 93. A native of Aylesbury, Dr Locke qualified L.R.C.P. Ed. in 1881, took the L.S.A. in the same year, and the M.R.C.S. in 1886. He spent his early years in general practice in Princes Risborough and later in London. In 1893 he settled at Hastings, where he practised until his retirement in 1930. A man of wide interests, Dr Locke took a keen and energetic part in local affairs. He was appointed a Justice of the Peace in 1906 and sat regularly on the Hastings Bench until shortly before the war. He was also vice chairman of the old school board and chairman of the local branch of the Royal Surgical Aid Society, a post he held for many years. His greatest pleasure and interest was in the St John Ambulance Brigade, which owes him a deep debt of gratitude for his devotion to its development. For his part in this work he was made a Commander of the Order of the Hospital of St John of Jerusalem, an honour of which he was justly proud. Dr Locke was a member of the British Medical Association for forty years and took a prominent part in the activities of the Hastings Division, which he represented at the Annual Representative Meetings in 1912, 1913 and 1921. He was president of the Sussex Branch in 1918. He was also an ex-president of the East Sussex Medico-Chirurgical Society. Dr Locke is survived by a son and three daughters. Mrs Locke died nineteen years ago and his second son was killed in the first world war.

With the death of Dr IZSET MEAD HAYTHORNTHWAITE at the age of 87 at King's Langley, Herts, on Nov 24, one more link is severed with the days of women's emancipation. She in 1886 being the second woman to receive the triple qualification of Edinburgh and Glasgow. Engaged by the Zenana Bible and Medical Mission, she took postgraduate training in Vienna in midwifery and diseases of the eyes and ears attending, among others, the clinic of Prof. Politzer. In 1887 she was house-surgeon at the New Hospital for Women (which stood on the present site of Marblebone Station) under Dr Elizabeth Garrett Anderson and after that went to India. For five years she worked in the Lady Kinnaird Hospital for Women and Children with Miss Haskey (now Mrs Birket) to whose efforts the building of that hospital was largely due. In 1892 she married the Rev. J. P. Haythornthwaite and this, with a trip to New Zealand, put a term to regular medical work, but while in Agra 1893-1911 as wife of the Principal of St John's College she found ample opportunity to minister to the families of missionaries as well as having five children of her own. In 1915 her eldest son was killed in action in France and she, though by now getting old, somewhat infirm and suffering from the disability of a malunited fracture of the wrist and running a home with little help, did her best to fill a place in the depleted ranks of doctors serving the civilian population. During 1915-18 she filled the posts of clinical assistant at the Garrett Anderson Hospital for three months, six months as resident medical officer at the Nayland Sanatorium, filled a short gap at the Rosa Morrison Home of Recovery at Barnet, was for three years visiting physician at the Four Boroughs maternity clinic and first doctor to the King's Langley antenatal clinic. Predeceased by her husband by many years she leaves three children, two of them doctors in India, who mourn the loss of a personality of more than ordinary character, ability and sweetness.

Dr WILLIAM MURRAY, who died at Hesse on Nov 29, was a native of Montrose, he studied in the University of Edinburgh, graduated in 1891 and took the M.D. in 1895. After being house surgeon at Tottenham Hospital, he went to sea for three years in the service of the P. & O., and then came to Hesse in partnership with the late Dr Fraser, whom he later succeeded. He was a member of the Hull Medical Society and of the B.M.A. from 1895 till the day of his death, being chairman of the East Yorkshire Division in 1924-25. For many years he was honorary medical officer to the Hull Seamen's and General Orphanage and devoted much time and thought to the interests of that charity and to the well-being of the children. In 1903 he joined the Territorial Army and reached the rank of lieutenant colonel in the 2nd Northumbrian Brigade, R.F.A. He was officer in charge of the Central Hospital in Hull until it was closed down. Dr Murray retired from practice in 1937, but on the outbreak of war again interested himself in lecturing to the St John's Ambulance and in other professional activities. He will be greatly missed by a host of ex-patients and personal friends in Hesse and the surrounding district. Everyone admired his wide learning, his phenomenal memory, and his powers as a raconteur, but perhaps his most endearing characteristics were his unfailing cheerfulness and his keenness while at work or play. He was a good horseman, a pioneer motorist, and a fisherman to whom the mysteries of flies and fish were an open book.

Dr ROBERT LEE MOORE, J.P., died at his home in Bangor on Nov 30. For over half a century Dr Moore carried on an extensive practice in Bangor. He was a skilful family doctor with a real interest in the welfare of his patients. A native of Belfast, he was educated at the Royal Belfast Academical Institution and at Liverpool, qualifying in 1890. He was closely associated with the Bangor Hospital from its beginning as a small cottage hospital, and was a life governor of the present hospital. He had an inexhaustible fund of stories about old Bangor personalities and events, and he was an authority on County Down folklore and dialect. In his youth Dr Moore was a noted Association football player and athlete, and throughout his long life his love of sport continued. He was a member of the Royal Ulster Yacht Club and a life member of Bangor Golf Club. A prominent and highly esteemed figure in the Masonic Order, he occupied most of its important offices. He is survived by his wife, three daughters and two sons, one of whom is Dr B. P. L. Moore, clinical pathologist to the Mater Hospital, Belfast. A third son died in Java while a prisoner of war in Japanese hands.

Dr GEORGE STEWART CLARK, of Edinburgh, who died on Dec 17, had been school medical officer for Midlothian and Peebles from 1924 until his retirement early this year. He had previously held a similar post at Roxburgh for four years. Dr Clark graduated at Edinburgh University, and was for two years assistant medical officer at the Edinburgh City Hospital. For six months he was junior assistant to the Professor of Public Health, Edinburgh University, and for one year senior assistant medical officer at Monsall Hospital, Manchester. He worked under the Edinburgh education authority for nearly eleven years as assistant medical officer, and had served for four years with the R.A.M.C. Dr Clark, who was 72 years of age, is survived by his widow and a son and daughter.

Dr JOHN FLASBY LAWRENCE WHITTINGDALE, the doyen of the medical profession in Dorset, died on Dec 11. It is given to few men to have so many years of life and so many years of active professional work. Born at Thornton in Lonsdale on Oct 6 1858, he was educated at Richmond School and at Gonville and Caius Cambridge. He qualified at Edinburgh in 1883 and became house-surgeon to Prof. John Chiene and afterwards to Sir Halliday Croome at the Lying-in Hospital. He did two trips as surgeon to the P. & O. Company, being shipwrecked off Trincomalee. After a year as assistant in Maidstone Dr Whittingdale came to Sherborne in 1889, where for fifty years he was actively engaged in one of the largest medical practices in the county. He held the appointments of public vaccinator and parish medical officer to two large districts, was medical officer to Sherborne School, to Sherborne School for Girls, the post office, and the almshouse. During the whole of his active life he was surgeon to the Yeatman Hospital and on his retirement was elected consulting surgeon and vice-president of the hospital. For fifty years he was a mainstay of the Dorset Division of the B.M.A., regularly attending all meetings. He held all the offices in succession both in the Division and in the Branch. From 1914-18 he was Chairman of the Local Medical War Committee and occupied this position in the early days of the recent war until ill health

compelled him to retire. He was at one time much occupied in local affairs and served as chairman of the Sherborne UDC. Interested in apiculture he was for many years chairman of the local beekeepers association. A lifelong devotion to field sports occupied his scanty leisure. He was lamed permanently by a hunting accident in 1896, but shot and fished until his eightieth year and had a profound knowledge of game birds and fishes. It is remarkable that a man so fully occupied with medical practice in a wide district could still manage to be interested in and find the time for so many other activities. He will be greatly missed in Sherborne and by the profession in Dorset.

The late Dr HARRY ATKIN DUNKERLEY was born on Dec 26, 1883 son of John Whiteley Dunkerley, LDS, a founder of the Manchester Dental Hospital. Educated at the Central High School and Victoria University, Manchester, he graduated MB, ChB in 1912. As a student, being unable to take part in outdoor sports, he took keen interest in the RAMCV, and was in the 2nd Western General Hospital, reaching the rank of staff sergeant, RAMCT. After four years as a colliery surgeon he returned to Manchester in 1917 and was in practice there for 22 years. Glaucoma in 1925 resulted in blindness of the left eye, he also had myopia to a high degree. Progressive myopia and large scotomatous areas in the visual field of the right eye eventually made it impossible to discharge professional duties efficiently, and through help from the National Insurance Defence Trust he was enabled to retire in 1939 after an overwhelming struggle against affliction in later years of active professional life.

Dr VIKTOR POLLAK, who died suddenly on May 7 this year, was born at Rokicany, Austria-Hungary, on March 18, 1884. After his schooling in Prague he entered the University there, graduating MD in 1908. The following six years he spent in hospital appointments in Prague, Vienna, and in the Austrian Army. He was assistant to such famous men as Yaksch, Schauter, and Knopfmacher. Immediately before the first European war he was working with Wertheim. He was surgeon in the Austro-Hungarian Army throughout the 1914-18 war, serving with distinction on the Russian and Italian fronts. After the war he set up in private practice in Vienna, largely among women and children. After twenty years' busy and valued work he had to flee his beloved Vienna in 1938, to find refuge first in Prague, then in England. For the last four years he held a responsible post on the staff of the North Middlesex Hospital. A colleague writes. It is remarkable what a warm place Viktor Pollak won in all our hearts. How bravely he faced the difficulties of new work in a strange land—difficulties which would have daunted many a younger man. To say he adapted himself to his new work would not be accurate—he did up to a point, and then all around him joyfully adapted their ways to his. His English was emphatic and picturesque and well became his distinguished, rather military bearing. He was, by the way, very proud of his soldiering in those far-off days before the first war in the old Austro-Hungarian Army. He often looked back wistfully to the old empire. It was good to hear him talk of the medical giants of Vienna—he had worked with men who knew them all—Billroth, Czerny, Mikulicz. Pollak took a great pride in his work—many a time he was chaffed in the mess about some diagnosis only to be vindicated in the operating theatre or post-mortem room. His accurate clinical accounts were often embellished by the most excellent sketches of the condition found. These rapid vivid drawings were the envy and joy of his colleagues. He died as he would wish, in harness with no warning, having won the love and admiration of all who worked with him.

We report with regret the sudden death on Aug 19, at Montego Bay, Jamaica, of Dr EUGENE DE MONTEVIN GIDEON, formerly MOH of St James, a position he recently relinquished to become medical superintendent of West Indies Sugar Estates, Ltd, a division of Tate and Lyle, Ltd. Born in 1885 he was educated at Bedford Grammar School and at Toronto University, graduating MB with honours in 1907. Returning to England he took postgraduate courses at the London and at the Queen Charlotte Hospital, obtaining the MRCS, LRCP in 1908. After a few years in private practice he entered the Jamaica Medical Service and was medical officer of the Buff Bay district for many years. During this period he was selected by the Government to represent Jamaica at the British West Indies Medical Conference at Georgetown, British Guiana, in 1921. He practised in partnership with his brother, Dr Cyril Gideon, in Kingston for a short time, and acted as MOH for the Kingston and St Andrew Corporation before taking up his duties at Montego Bay. Eugene Gideon

joined the BMA in 1909 soon after qualifying and was an active member up to the time of his death. He held office as a member of council from 1932-9, was chairman of the obstetric section, and was elected president of the branch in 1934. By his wise counsel, his tact, and his felicity of speech he rendered invaluable service to the Association, and did much to bring about happy solutions of the many problems which the local branch had to face in its dealings with the Government. His presidential address on 'Fraternity in Medicine' was an appeal to the members to improve social and professional relations, and with his charming manner and engaging personality he was himself a brilliant example of the precepts he advocated in this respect. He was seen perhaps at his best when he presided at a dinner given in honour of the late Lord Moynihan in 1935, and in the same year at a reception for the visiting members of the Pan-American Medical Association. He did splendid work, too, when the then General Secretary the late Dr G C Anderson, visited Jamaica in 1939. Dr Gideon was a man of outstanding professional ability, loyal to the profession which he loved, and sympathetic always to his colleagues and friends. The medical profession and indeed, the whole island have suffered a great loss by his death.—G I L

Wing Cmdr H M Stanley Turner writes. It was with deep regret that I heard of T S RIPPON'S death (Dec 14, p 922). We were associated for many years, and he was one of my officers in the Middle East. He has a unique claim to fame in that he must undoubtedly be regarded as the father of the Royal Air Force Medical Branch. At the time the Royal Air Force was constituted as a separate Service in 1918 the question arose as to whether it should or should not have its own separate medical service. It was Rippon who made out an overwhelming case for a separate medical service, and the subsequent history of the R A F Medical Branch has fully justified this claim, both in the intervening period between the two wars and especially in the war recently ended. Rippon had a very shrewd, scientific mind which foresaw clearly the highly specialized work which a R A F Medical Service would be called upon to undertake and the lines of research which as the Service developed, must necessarily be followed. He was a delightful colleague with whom to work, with a quaint sense of humour which never failed even under the most adverse circumstances, and he is entitled to a niche as one of the pioneers in aeronautical medicine, a branch which even to-day is only in its infancy. Those of us who knew him well will always regard him with respect and affection.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated

UNIVERSITY OF LONDON

The title of Professor Emeritus of Surgery in the University has been conferred on G Grey Turner LL.D. M.S., F.R.C.S. on his retirement from the Chair of Surgery, which he has held at the British Postgraduate Medical School since 1934.

The title of Professor Emeritus of Physics in the University has been conferred on Sydney Russ, D.Sc. on his retirement from the Chair of Physics which he has held at the Middlesex Hospital Medical School since 1920. He is succeeded in the Chair of Physics by J. E. Roberts D.Sc. Ph.D.

Mrs Meave Kenny M.D., F.R.C.O.G., has been appointed to the University Readership in Obstetrics and Gynaecology tenable at the British Postgraduate Medical School from Oct 1 1946.

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY—P. E. S. Palmer, W. Pimblett, M. P. Shapiro. Part I: V. Berman, E. B. Brennan, T. Chopping, J. M. Corall, P. M. Davies, J. Dawson, H. F. T. Deane, A. Greig, T. Holroyd, C. H. Kitchen, M. J. Meyer, R. O. Murray, D. H. Nelson, W. D. Nichol, J. H. O'Connell, R. H. Owen, B. Prasad, C. Stuart, P. Teitmar, A. Volpowitz, M. C. Wood, W. B. Young.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examination indicated:

FR. AL. M. B. CH. B.—Joan Hampson (second-class honours), C. J. T. Archer, Kathleen Burn, H. S. Coulsting, Dorothy Davies, Vera A. Dearden, O. G. Lodge, C. J. Glancy, A. B. Haward, J. B. Howard, S. T. Lunt, J. Needoff, E. L. Peel, N. W. Preston, Kathleen Rampling, A. E. Snellswell, Lorinda Wallace, Joan M. Waterfall. Part I: Sheila A. Costello, F. J. Davies, A. Kinsey, J. E. Barry, S. L. Royce, P. Wolf, K. S. Holt.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following Hunterian Lectures will be delivered at the College Lincoln's Inn Fields, W.C. on Thursdays at 5 p.m.: Jan 9, Prof. J. B. Macalpine 'Growths of the Renal Pelvis and Ureter', Jan 16, Prof. R. H. Franklin, 'Congenital Atresia of the Oesophagus', Jan 23, Prof. H. A. Haxton 'Regeneration after Sympathectomy and its effects in Raynaud's Disease', Jan 30, Prof. John Hawkins 'Movement of the Diaphragm after Operation'. The lectures are open to those attending courses in the College and to all other medical practitioners and advanced students.

A course of lectures in ophthalmology will be held at the College and will be given as follows: Jan 20, at 3.45 and 5 p.m.; Jan 21, at 3.45 and 5 p.m.; Jan 22, at 3.45 and 5 p.m.; Jan 23, at 3.45 and 6.15 p.m.; Jan 24, at 3.45 and 5 p.m.; Jan 27, at 3.45 and 5 p.m. The fee for the whole course is £5 5s. Fellows and Members of the College and Licentiates in Dental Surgery will be admitted on payment of a fee of £3 3s. Applications, accompanied by a cheque for £5 5s. or £3 3s. should be sent to the assistant secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.2.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

The annual meeting of the College was held on Dec 5 when Dr D. M. Lyon was re-elected President. Drs W. D. D. Small, S. P. Davidson, J. D. S. Cameron, H. L. Wallace, I. G. W. Hill and D. K. Henderson were elected to form the Council of the College for the ensuing year. Dr W. D. D. Small was nominated Vice President.

SOCIETY OF APOTHECARIES OF LONDON

At a recent meeting of the Court of Assistants with Dr C. T. Parsons Master in the chair the announcement of the death of Sir Walter Langdon Brown, Honorary Freeman of the Society, was received with great regret. Dr J. P. Hedley was reappointed as the Society's representative on the General Medical Council.

Common Hall was recently called to discuss the proposal to admit medical women to the Yeomanry and Liver of the Society. The result of the vote was reported to the court, which has decided that medical women shall be admitted.

The Diploma of Mastery of Midwifery was awarded by examination to J. G. Hunt.

The Diploma in Industrial Health was granted by examination to F. H. Tyrer and J. B. Lyne.

The Diploma of L.M.S.S.A. was granted upon examination to the following successful candidates: I. J. R. Musson, H. F. Goldmar, H. M. Price, J. O. Kelsey, G. A. May, A. H. J. Whitehouse, H. Freeman, J. A. Sodipo, R. M. Holmes, T. C. McC. G. H. G. H. S. L. O. Jackson.

FACULTY OF RADIOLOGISTS

The following candidates have satisfied the Board at the recent examination for the Fellowship: R. J. Keating and G. S. M. (Radiodiagnosis).

The Services

Lieut.-Gen. Sir W. P. MacArthur K.C.B., D.S.O., O.B.E., retired pay, to be Colonel Commandant, R.A.M.C., in succession to Lieut.-Gen. Sir James Hartigan K.C.B., C.M.G., D.S.O. retired pay, who attained the age limit for the appointment on that date.

Surg. Cmdr. R. H. Enoch R.N.V.R., has been awarded the R.N.V.R. Officers' Decoration.

The following officers have been mentioned in dispatches in recognition of gallant and distinguished services in Malaya in 1942: Col. J. M. Mitchell, O.B.E., Lieut.-Col. L. T. Pearson, Lieut.-Col. (Temp.) W. J. L. Neal, O.B.E., M.C., Lieut.-Col. (Acting) E. G. Hardwood and W. G. Kennedy, Majors K. F. Alford and L. Feinholz, Major (Acting) S. G. Nardell, Capt. Arora, O. F. Campbell, A. K. Marwat and A. Roy, and Assistant Surgeons R. R. Braganza and G. McG. J. Hartley, I.A.M.C.

Medical News

Dr Innes Pearse will speak on the Peckham Health Centre at a meeting of the London Association of the Medical Women's Federation in the Hastings Hall of B.M.A. House on Tuesday, Jan 7 at 8.30 p.m. The next meeting will be held on Wednesday, Feb 5 when Miss D. J. Collier will speak on the influence of war experience on everyday ear and throat treatment.

A meeting of the Faculty of Homoeopathy will be held at the London Homoeopathic Hospital, Great Ormond Street, W.C. on Thursday, Jan 9 at 5 p.m., when Dr Tatiana Hardy will give an address on Allergy.

The London Council of Social Service (7, Bayley Street, Bedford Square, W.C.1) has arranged a conference on 'Special Forms of Catering for the Aged Invalids and Infirm' to be held at Bonnington Hotel, Southampton Row, W.C., on Saturday, Jan 18, at 10.20 a.m., with Lord Amulree M.D., F.R.C.P., in the chair.

The Central Office of Information (Montagu Mansions, Crawford Street, W.1) has designed an exhibition for the Ministry of Labour and National Service, the Ministry of Health, and the Ministry of Pensions entitled 'And So To Work' which will be open on the exhibition site in Oxford Street, London W., on weekdays from 11 a.m. to 7 p.m. from Jan 8 to Feb 1 inclusive. The exhibition will show the rehabilitation and resettlement of the disabled from hospital to training centre and so to work, and demonstrations will be given by physiotherapists, occupational therapists, and remedial gymnasts. Questions will be answered by experts at the information centre in the exhibition.

An Ethiopian Exhibition of arts and crafts, the first of its kind in England, will be held for a fortnight from Jan 20 under the auspices of the Princess Tsehai Memorial Hospital Council at Fovle's Bookshop, Charing Cross Road, W.C.2. Lectures on the Ethiopian language, literature, Church, etc., will be given; the exhibit will include specimens of the fine and applied arts, photographs and children's drawings. The committee would be grateful for the loan of further exhibits.

A meeting of the Association of Industrial Medical Officers will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C. on Friday, Jan 24 at 4 p.m. At 5 p.m. on the same day there will be a joint meeting with the School Medical Service Group of the Society of Medical Officers of Health when the subject for discussion will be 'The Change from School to Industry', to be opened by Drs A. A. E. Newth and T. A. Lloyd Davies. On Saturday, Jan 25 at 10.20 a.m. Mr R. H. Young will give an address on 'The Diagnosis, Pathology and Treatment of Intervertebral Discs' illustrated by a colour film.

Messrs. Boos have endowed for seven years a research fellowship of £1,000 per annum at St. Mary's Hospital. The board of management of the hospital and the council of the inoculation department have elected R. E. B. Hudson M.B., B.S. to be the first Boos Research Fellow.

Messrs. Butterfords Wellcome and Co. announce the adoption of a five-day week for their London offices and warehouse. Until further notice an emergency staff will be in attendance on Saturday mornings at 12, Red Lion Square, W.C.1 (Tel. Chancery 6621) from 9 a.m. to 12.20 p.m., to deal with urgent orders.

Mr Joseph Cunningham F.R.C.S., F.R.A.C.S., and his wife Mrs Annie Broomhall Cunningham M.B., have given the house and ground of Broome Park, Beaconsfield, Bucks, to the Electrical Industries Benevolent Association as a home for old people to serve as a memorial to their son James Ernest Cunningham, who was killed in a road accident in 1941.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec 14

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1946					1945 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Includes primary form for England and Wales London (administrative county) and Northern Ireland

‡ Includes puerperal fever for England and Wales and Eire

It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct 26 Nov 2, 9 16 23 30, Dec 7 and 14

EPIDEMIOLOGICAL NOTES

Neonatal Diarrhoea

The only other outbreak since our report of last week (Dec 28 p 1009) is at Stoke-on Trent

At the beginning of December the 30-bed maternity unit there had to deal with some 35 cases. During the first week of December two of these mothers complained of diarrhoea and by the end of the second week nearly a dozen infants were affected. In the infants the onset was explosive and there have now been four deaths. The four infants were perhaps a week old when the diarrhoea began, in each case the condition terminated fatally after ten or fourteen days. Altogether 10 mothers, 36 infants and 2 members of the staff appear to have been affected. Bacteriological investigation has not as yet revealed any causative organism. Clearly this outbreak is very like the one at Oxford. It has been of moderate severity with a case fatality rate not nearly so high as that in the Leicestershire outbreak.

There have been no further developments in Leicestershire and at Oxford and Preston the maternity units have now reopened.

Discussion of Table

In England and Wales an increase was recorded in the notifications of measles 491 and scarlet fever 115, and there was a decrease in the incidence of whooping cough 119.

An increase in the incidence of measles was recorded throughout the country, the largest rises were Kent 119, Yorkshire North Riding 109 and Essex 88. In contrast to the general trend large decreases were recorded for Buckinghamshire 103 and Northumberland 92.

The rise in the notifications of scarlet fever was mainly contributed by the West Midland counties the largest increase was Warwickshire 30. Small increases in the number of cases of whooping cough were noted in most counties, the largest variations in the local trends were an increase in Lancashire 41 and a decrease in Yorkshire West Riding 30.

There was an outbreak of diphtheria in Lancashire Orrell UD where the notifications rose from 1 to 29. A fall in the incidence of diphtheria was recorded in London 15 and Durham 10. London had 13 (Chelsea 6) cases of dysentery.

In Scotland increases were reported in the notifications of measles 93 and whooping-cough 26 while a decrease was recorded for scarlet fever 28. An increase of 10 in the incidence of diphtheria occurred in the city of Glasgow.

In Eire the chief features of the returns were decreases of 23 in cases of diarrhoea and enteritis and of 30 in cases of whooping-cough. The returns for diarrhoea and enteritis were the lowest since the end of August.

In Northern Ireland a further increase of 40 was recorded in the outbreak of measles in Belfast CB.

Quarterly Return for England and Wales

The birth rate during the September quarter was 19.7 per 1 000 and was the highest recorded for any quarter since 1921. Infant mortality was 35 per 1 000 live births and was the lowest rate ever recorded, being 7 below the average for the third quarters of the ten preceding years. The general death rate was 9.3 per 1 000 which was 0.3 above the corresponding quarter of 1945 but 0.5 below the average of the third quarters for 1940-4.

Week Ending December 21

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,201, whooping cough 1,586, diphtheria 242, measles 7,728, acute pneumonia 741, cerebrospinal fever 29, dysentery 62, acute poliomyelitis 13, paratyphoid 6, typhoid 4.

A Ministry of Health Circular (230/46) to local authorities points out that under the terms of the National Health Service Act the Minister becomes responsible, from the day appointed for its operation, for the provision of hospital and specialist services as defined by section 3 (1) of the Act. In general the Regional Hospital Boards will administer these services, and regulations will be made under section 68 (1) transferring officers employed immediately before the appointed day "solely or mainly at or for the purposes of any hospital transferred to the Minister under the Act (other than teaching hospitals)" to the Boards. The officers referred to include (a) those employed at central offices or elsewhere in the authority's hospital service, as well as (b) those on the staff of individual hospitals. Authorities are asked to provide particulars, not later than Jan 31 1947, of officers in the former class, whom they consider likely to be liable to transfer, excluding officers of the mental hospital and mental deficiency services, who will be the subject of a separate inquiry.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Umbilical Swelling

Q—A male child was born apparently healthy but separation of the cord was delayed and a fleshy finger of tissue remained protruding from the umbilicus. Now three months later all that is visible is a small rounded knob which has a somewhat cystic appearance. The umbilicus however weeps continually and sometimes there is a slight flush around it suggesting inflammation. Is it safe to use silver nitrate to cauterize the umbilicus or is there any danger of eroding a Meckel's diverticulum and producing a faecal fistula?

A—The first point to determine is whether the constant weeping is or is not due to the presence of a fistula. Since there is no faecal discharge there can hardly be any opening of the vitello intestinal duct but one must remember that occasionally the opening of a patent urachus may be found at the umbilicus. It is not stated whether the swelling is bright red in colour, if it were so one might be dealing with the small denoma which is sometimes found at the umbilicus in young infants. The most likely explanation is that the swelling is a granuloma which ought to develop into fibrous tissue if the parts are kept clean and aseptic. It is unlikely that the application of silver nitrate would do harm, but perhaps the shrivelling up of the tumour might better be obtained by painting with a solution of alum or dilute formalin. If, however the condition persists, it should be dealt with by a competent surgeon who would make quite sure of the deep relations of the swelling.

Pigmentation in Pregnancy and Lactation

Q—A patient of mine had marked pigmentation of the face particularly over the eyebrows and round the mouth when she was pregnant. Now that the baby is seven months old (breast-fed) the pigmentation is a little lighter but still persists. Can anything be done about it?

A—All authorities agree that there is a tendency to pigmentation during pregnancy. It is suggested that this is due to expansion of the melanophores or pigment-bearing cells of the skin probably in response to a hormone derived from the posterior pituitary. The most severe and distressing form—chloasma gravidarum—affects the face in the form of yellow or bronze patches. Ballantyne J W and Browne F J (*Trans Edin Obstet Soc* 1919, 40 74) showed that blondes and brunettes are equally liable to this affection thus disposing of the commonly held idea that such pigmentation occurs mainly in those whose skins are dark.

The pigmentation of the face generally clears up within a few months of confinement. De Lee J B (*Principles and Practice of Obstetrics* 1940 seventh edition Philadelphia), states that it tends to disappear when the menses are re-established but mentions that it may persist for years. This particular patient may therefore expect improvement when lactation is discontinued. No treatment seems to be of any avail but the judicious use of cosmetics and possibly of the newer preparations which are supplied in the form of a flat cake applied with a damp sponge may help to cover the dark patches and thus alleviate the patient's distress.

Menstrual Mollimina

Q—A woman of 30 with one child of 2 years has had for the past five months flooding of thin almost colourless fluid at her periods. After the third day the loss becomes gradually normal in colour amount and consistency. Is there any explanation or treatment for this condition?

A—The fluid is probably the natural secretion of the tubal body of uterus and cervix—one or all. This secretion is at its maximum in the days preceding the onset of the menstrual flow proper and to a limited extent is a normal phenomenon. Thorough examination is indicated to exclude erosion of the

cervix chronic cervicitis and any lesion causing pelvic congestion. If the findings are negative it is doubtful whether any treatment is necessary apart from simple measures to reduce pelvic congestion. Saline aperients active physical exercise and cold baths might help.

It would be interesting to know if this patient shows during the premenstrual phase signs of abnormal fluid retention—increased weight oedema and a sensation of abdominal swelling. If so it is just possible that the discharge might be part of the general excretion of previously retained fluid which usually occurs at the onset of menstruation in such cases. If this is so, then restriction of the intake of fluid and sodium salts for seven to ten days before menstruation is indicated.

Vitamin A Concentrates

Q—How can vitamin A be supplied to a boy showing signs of A deficiency who is allergic to both milk and fish?

A—Vitamin A concentrates which do not contain fish oil (e.g., 'carotene tabloid', each tablet of which contains 4,500 i.u.) are available. Foods which are good sources of vitamin A and their contents per 3½ oz (100 g) are as follows: spinach 5,000 i.u., carrot 2,000 i.u., tomato 14 to 16,000 i.u., cabbage 960 i.u., and orange juice 3–400 i.u. Animal livers are also good sources of vitamin A containing from 2–45,000 i.u. per oz (30 g) depending on the type of liver (*Hutchinson's Food and Principles of Dietetics* 1941 p 112).

Increase in Tuberculosis

Q—What were the notifications of all forms of tuberculosis (pulmonary and non-pulmonary) for the years 1939–45? What is the explanation of the increase if any?

A—The figures for 1945 are not yet available. The notifications for the six years 1939 to 1944 were 25,355, 26,260, 28,966, 29,560, 30,121, and 30,044. The number of persons not notified before death but dying of tuberculosis during these years were 2,901, 3,395, 4,383, 3,971, 3,780, and 3,468. The introduction of mass radiography with the consequent earlier discovery of the disease was at first thought to account for the rise but this suggestion cannot explain the persistent higher incidence and there has undoubtedly been an increase in tuberculosis. This increase is generally attributed to the conditions of life during the war but it is impossible to assess the relative importance of the factors such as black-out and lack of ventilation long hours of work, diet etc. which may have contributed.

Rainbow Haloes

Q—A patient aged 65 has been seeing rainbow haloes around lights—the red outside the violet inside—with each eye separately with both eyes and with or without glasses. There is no question of glaucoma or cataract. What is the explanation?

A—Any structure within the eye which acts as a diffraction grating will produce a rainbow-like halo with the red outside and the blue inside. This may equally be produced by a layer of cells or by droplets of fluid. These two types of halo may be differentiated by passing a stenopæic slit slowly across the pupil. In the former only sectors of the halo diametrically opposed to each other will be seen which give the appearance of rotating as the slit passes across the pupil. The latter type of halo remains circular and only varies in intensity with the movement of the slit. Haloes may be due to physiological changes in the corneal epithelium and endothelium lens opacities and possibly fibrillary intersections of the vitreous or to mucus, blood pus, or small air bubbles in the lacrimal secretion or other material on the surface of the cornea or also to oedema of the deeper layers of the corneal epithelium due to glaucoma or photophthalmia from exposure to ultra-violet light.

The diameters of haloes vary, and when measured from the point of origin of the causal incident light the yellow ring of a lenticular halo subtends 6° to 7°. The ring due to material on the surface of the cornea is large—up to 14°—and of course disappears when the cornea is cleaned. A halo without differentiation in colour is common in normal eyes under ideal conditions.

Treatment of Syphilis

Q—*The wife of a G.P.I. has a strongly positive Wassermann reaction but no clinical signs of syphilitic infection. How should she be treated?*

A—With the somewhat meagre details available this question is difficult to answer. We should like to know the age of the patient and her obstetrical history, whether she is past the child-bearing age, and whether there have been any miscarriages. Assuming that the patient is syphilitic but has no cardiovascular lesion and has passed the menopause everything depends on the state of her cerebrospinal fluid. If this is completely negative (Wassermann, cells protein, and colloidal gold reaction) it seems doubtful if any treatment is necessary. As an insurance one or two courses of bismuth each year for a few years might be worth while, each course to consist of ten weekly injections of 0.25 g of an insoluble salt. On the other hand if the fluid is positive, and more particularly if the pathological changes are well marked, active treatment is indicated without delay. This should consist of penicillin and fever therapy—preferably artificially induced malaria. At least 4 million units of penicillin should be given by intramuscular injection, either in doses of 40 000 units three hourly or in doses of 300 000 units twice daily, the malaria should be induced by injection of infected blood and about twelve paroxysms allowed before it is terminated. The follow-up should include examination of the cerebrospinal fluid every six months.

Chemotherapy and Appendicitis

Q—*Now that we have unlimited penicillin and a large range of sulphonamides what is considered the best treatment for acute perforated appendicitis and general peritonitis? Should penicillin be given and which sulphonamide is advised in what dosage (assuming operation has been carried out)?*

A—The answer to this question is implicit in the bracketed phrase at the end of the paragraph. The treatment of acute perforated appendicitis and general peritonitis is still the operation of appendicectomy followed by nasal suction drainage of the upper alimentary tract and adequate fluid and salt replacement by the intravenous route. Penicillin and sulphonamides have added to this management only in slight degree. The systematic administration of penicillin will prevent certain of the pulmonary complications of peritonitis and will control any septicaemic manifestations. This is true even when the dominant peritoneal organism is penicillin resistant, for the metastatic lesions in the chest may well be due to a secondary and penicillin-sensitive infection. Penicillin given systematically does not appear in great concentration in the peritoneal cavity, and if given locally it will be inactivated by the penicillin resistant coliform organisms which complicate peritonitis in its later stages. The soluble sulphonamides may be given by way of the intravenous drip, it has not been clearly shown that the local application of sulphonamides to the peritoneum at the time of operation reduces the mortality significantly. *Str. faecalis* is highly resistant to penicillin and for bacterial stasis of this organism the concentration of penicillin required is difficult to obtain in the peritoneal cavity.

Ultraviolet Irradiation Without Goggles

Q—*Can a carbon arc sunlight lamp be used with safety at say 2 ft (60 cm) from the face for five to ten minutes on alternate days without protective goggles provided the eyelids are kept closed?*

A—If the "carbon arc sunlight lamp" in question does not produce more than a first-degree reaction on the face under the stated conditions, there is no need to wear goggles provided the eyes are kept shut. There always exists the possibility of producing—with the same dosage—a second degree reaction of the more delicate skin of the eyelids. The resulting discomfort and oedema of the loose tissues are easily avoided by smearing the eyelids with cold cream or zinc oxide ointment before irradiation.

Incidentally, it is more effective and more aesthetic to treat the face in two halves with the lamp not directly in front of the patient but over to one side. This can be achieved by making the patient face the lamp and then turn the head through 45° one way, then the other, for the same exposure.

Letters and Notes

Panophthalmitis After Cataract Operations

Dr J T MACLACHLAN (Glasgow) writes: I am of opinion that if Lister's antiseptic technique is employed in operations on the eye panophthalmitis and other complications would not arise. Dr William MacKenzie the famous Glasgow oculist, devised over 100 years ago an excellent antiseptic lotion for diseases of the eye. MacKenzie's lotion consists of bichloride of mercury 1 gr (65 mg) chloride of ammonium 6 gr (400 mg), coccus cacti (cochineal) 1½ gr (100 mg), Aq 6 oz (170 ml). Of this lotion a little—about a spoonful—is diluted with equal parts of warm water, and the eye bathed several times daily with a piece of linen or sponge and the head tilted back and some of the lotion allowed to run into the eye. If MacKenzie's lotion were used several times daily for one week before operation and for some time after the operation, I believe septic complications would not arise. To prevent haemorrhage in the eye after operations for cataract, if the blood pressure is high it can be safely reduced to 120 by giving "liq. trinitrin" 1 or 2 min (0.06 or 0.12 ml) along with some spirits of sweet nitre some time before and after the operation.

Definition of Health

Mr PATRICK SLATER writes: The *Oxford English Dictionary* authorizes the use of the word 'health' to indicate a variable state. I have never known anyone take etymological exception to the question: 'How is your health?' or to qualifying 'health' with such adjectives as excellent, good, indifferent or poor. Indeed, until some qualifying words are added an individual's health remains undefined. Moreover the World Health Organization the Ministry of Health the United States Public Health Service, etc., do not limit their terms of reference to states of complete physical, mental and social well being. If as a result of the decision of the World Health Organization the word "health" is henceforth to be applied only to such a state may I ask: Has the word any connotation whatever? What comprehensive term if any applies universally to all the observable conditions which approximate to or deviate from this perfect state? How can their decision be enforced?

Notes from Russia

Dr W P FORREST, chief medical officer of the UNRRA Mission to the Soviet Ukraine sends us the following medical news from Kiev. The late Prof Alexander Bogomoletz, whose work on the antitreticular cytoxic serum was outlined in this *Journal* (1943, 2, 203), has been succeeded as President of the Ukrainian Academy of Sciences by Alexander B. Palladin, a member of the Ukrainian Byelorussian and USSR Academies of Sciences and of the All Union Academy of Medical Sciences. Palladin has written over 150 scientific papers, and has founded many institutes and societies. His latest work is on vitamins and the biochemistry of muscular action. The son of Prof Bogomoletz is now director of the famous Kiev Institute of Pathological Physiology. Academician V P Filatov is once more installed in the partially reconstructed Filatov Ophthalmological Institute. He has arranged to do several articles in English on tissue therapy in ophthalmology and leprosy. There is an enormous demand here for literature to replace the medical libraries, which were almost completely destroyed by the invaders. Not only are old journals and books required to replace those lost, but recent and current books and journals are more than welcome. They can be sent c/o the UNRRA Mission to the Ukraine, or to I F Kononenko, People's Minister of Health Kiev, Ukrainian SSR.

Corrections

In the article headed "Classifying Causes of Death" (*Journal* Dec 21, 1946, p 957) the chairman of the Medical Advisory Committee Sir Ernest Rock Carling, should have been described as formerly Dean of Westminster Hospital Medical School.

A misprint occurred in the article by Dr A J Suchecki on "Allergic Reactions to Penicillin" (*Journal* Dec 21, 1946 p 938). Under the subheading "Review of the Literature" the word "included" in the second line from the end, should read "excluded".

THE VALUE OF PENICILLIN IN SURGERY

BY

G A G MITCHELL, OBE, ChM

Penicillin is the nearest approach to the ideal antiseptic yet discovered, and its value can scarcely be overestimated. But it has limitations, quite apart from the physical and chemical properties which hamper its preparation and administration. Only certain organisms are susceptible to it (although, fortunately, the sensitive group includes the majority of organisms of particular interest to the surgeon), and even these may not be inhibited or destroyed unless the drug is properly used and the appropriate ancillary treatments given. Good surgery is still essential, and the lavish expenditure of any chemotherapeutic agent will not purchase an indulgence for therapeutic sins.

Penicillin has now been tested in most of the likely and many of the unlikely conditions, and the literature abounds with records of its successes in small groups of selected cases, usually treated without contrasts or controls. Reports on large groups of surgical cases are almost confined to battle casualties because, until just over a year ago, the bulk of the world production of penicillin was devoted to the treatment of the Armed Forces of the Allies. The countless casualties provided a grim but instructive surgical surfeit, and many Army surgeons did not fail to utilize their unexampled opportunities. The figures quoted below are obtained from such sources.

Value of Penicillin in Prophylaxis

Penicillin, being more active and much safer in use, is a better prophylactic agent than the sulphonamides against the common pyogenic and anaerobic infections, but this theoretical superiority is unlikely to be exploited generally until simple oral methods of administration are perfected for use as aerosols in operating theatres or wards to prevent air-borne infections will be impossible until supplies become ample, although it may be employed more economically in the form of nose and throat sprays as Knott and Blaikley (1946) have suggested in an attempt to prevent infections produced by staphylococcal and streptococcal carriers. The penicillin pastilles recommended by MacGregor and Long (1944) and the tooth pastes or powders devised by Powell and Colquhoun (1945) may also be employed to combat the development of buccal, faucial and dental infections, but these methods have more medical than surgical applications and need not be further discussed.

So far penicillin has been given large-scale prophylactic trials only in battle casualties. All the dangerous pathogens commonly found in war wounds are penicillin-sensitive, and if penicillin can be maintained in contact with them in suitable concentration for a sufficient period of time these organisms should be inhibited or destroyed by the combined

effects of the drug and the normal body defence mechanisms. This knowledge was exploited through all stages of the campaign in NW Europe. Casualties were given parenteral or local penicillin, or both, at the most forward surgical levels as soon as practicable after wounding, and once a course of penicillin was started it was continued, no matter how or where the patient went, until a surgeon had decided that the treatment could be terminated or until the patient had been evacuated to an E M S hospital in the U.K. The preparation and administration of penicillin solutions and powders under active service conditions were not easy, and it was feared that complications due to penicillin-insensitive contaminants might be frequent. Actually, such contretemps were astonishingly few considering that at least 100,000 soldiers received penicillin treatment (Mitchell, 1945), and, apart from some impure batches which produced needless pain and irritation, penicillin justified in every way the remarkable claims made for it by Fleming, Florey, Cairns, and others. Reports from all sources contained comments on the marked absence of severe sepsis and the reduced incidence of all wound infections, and although better facilities, better surgery, better communications, and other factors deserved credit, few doubted that penicillin was the dominant factor in the control of infection—formerly the greatest single problem in war surgery.

Bacteriological Evidence—The clinical improvement was unquestioned, and confirmation was provided by bacteriological investigations (Porritt and Mitchell, 1946). In the Middle East campaigns "no growth" reports on the first wound swabs taken after admission of casualties to hospital were most uncommon. Thus in a series of 100 consecutive personal cases investigated in No. 1 Orthopaedic Centre, M.E.F., in 1942, a positive culture was obtained in every case. In the NW European (B.L.A.) campaigns of 1944-5, "no-growth" reports on wound cultures were common, and staphylococcal, and particularly streptococcal, infections were relatively uncommon (Porritt and Mitchell, 1946). Thus 268 out of 560 wound swabs taken from casualties who had nearly all received prophylactic penicillin gave "no growth" on culture. The findings are contrasted in Table I.

TABLE I

Organisms Isolated	M.E.F. Casualties	B.L.A. Casualties
Strep. cocci	68% (57% haem.)	5% (2% haem., 2% anti-haem.)
Staphylococci	55% (46% aureus)	22% (11% coag. — 5% coag. — 9% no details given)
Clostridia	23%	2%
Proteobacilli	16%	10%
Coliforms	6%	—
Proteus	1%	—
No growth	—	57%

In both the above-quoted series the infections were usually mixed, so the percentages merely give an indication of the incidence of the various organisms in the wounds. And it must be recorded that penicillinase was not employed in many of the cultures, so it is probable that a number of false negatives were obtained. Nevertheless, these laboratory findings confirmed the clinical impression that the great majority of the wounds were cleaner than were those commonly seen in former campaigns. Incidentally it is interesting to recall that in the war of 1914-18 haemolytic streptococci were the predominant pathogens (Fleming and Porteous, 1919).

Factors Influencing Results—Clearly it would be very important to discover the reason for the improvement, and after consideration of all possible factors influencing the occurrence of infection in wounds there is no doubt that the widespread prophylactic use of *both* parenteral and local penicillin at the most forward surgical levels in the NW European campaigns was the principal factor in producing the improved results. Time does not permit discussion of all these factors—nature of wounds and missiles, degree of contamination, terrain, climate, time-distance factors, resuscitation, anaesthesia, primary surgery, pre- and post-operative care, etc.—which do influence the state of wounds, but two common misconceptions must be corrected: (1) that the surgeons of 21 Army Group (the combined British and Canadian Armies constituting the so-called B.L.A.) were all specially experienced, and (2) that the time-distance factors were much more favourable in Europe than elsewhere.

1 The majority of the surgeons, anaesthetists, and transfusion officers who landed in Normandy in June, 1944, had no previous experience of field surgery, and while their work was generally excellent it was no better, for example, than that achieved by the Eighth Army surgeons. Yet their results, as judged by the condition of the wounds, were much better.

2 Some have assumed that more favourable time-distance factors in NW Europe explained all the improvements, it being ignored or forgotten that men wounded in the same theatre in 1940, even before the final disastrous days, had shown no comparable absence of sepsis. Two time-distance factors require consideration: (a) the interval between wounding and primary surgery, and (b) the interval between the primary surgery performed in forward units and the secondary surgery done in hospitals. These in turn are related to important subsidiary factors such as rest, frequency of dressings, etc.

The first interval is the more important in respect of prophylaxis, and, although this may surprise many, it was not significantly different in the N. African, Italian, or NW European theatres, being 12 to 14 hours on an average.

The second interval was often prolonged in the desert, especially in the earlier phases, and this probably explained the almost universal occurrence of moderate to severe wound sepsis. Exhausting journeys, lack of rest, inadequate fluids, frequent pain, and the irrepressible tendency to change dressings in each medical unit on the line of evacuation, all led to inevitable infection. But this state of affairs did not always prevail. At Alamein, where the greatest desert battle was fought, the front remained static for weeks on end. At that time casualties were evacuated to hospitals more easily and rapidly than was often possible during the campaigns in NW Europe, and the Medical Services were as efficient as anywhere during the war, yet the wounds were all infected to a greater rather than a lesser degree when the patients reached hospital.

Air transport was not used in evacuating the wounded from the battlefield to the forward surgical units a few miles

behind and therefore did not influence the more important time-distance factor from the prophylactic point of view—that between wounding and primary surgery. It did influence the period between primary and secondary surgery, however, as from the time of Alamein in 1942 onwards air-ambulances were used increasingly between forward and base medical units. It was possible to obtain information about this interval from special surgical reports submitted by many of the surgeons in 21 Army Group hospitals. Thus, of 2,153 men who had wound sutures performed, 1,290 were operated upon within 1 to 7 days of having been wounded, and 863 were operated upon 8 days or more after they had been wounded. It was the general rule to suture nearly every wound within 1 to 2 days after the patient had been admitted, so it is obvious that about 40% of the casualties in NW Europe did not reach a hospital where secondary closure was possible until about a week or more after they had been wounded. From late 1942 onwards the average intervals in other theatres were not greater.

Penicillin v. Sulphonamides in Prophylaxis—Many surgeons are still undecided about the relative value of sulphonamides and penicillin in prophylaxis, and assume that because the former are of great therapeutic value in many conditions they must also be very effective prophylactic agents. The evidence, however, favours the view that they usually prevent spreading or generalized infections from wounds, but have no appreciable effect on the incidence or severity of local infections. This was well exemplified in the later desert campaigns. By then the administration of prophylactic sulphanilamide was extremely efficient and, although the spreading infections commonly seen in the pre-sulphonamide phase were comparatively rare, the great majority of the wounds showed evidences of active local infection. In the NW European campaign both penicillin and sulphonamides were used and there was a remarkable change for the better in the condition of the wounds. As the one completely new factor was the prophylactic exploitation of penicillin, it must be accorded most credit for the dramatic improvement.

An attempt was made to discover whether penicillin alone was as effective in prophylaxis as penicillin plus sulphonamides. Once the former was freely available it seemed to be unnecessary to give both if penicillin alone was equally effective, especially as the sulphonamides occasionally produced annoying or even dangerous complications. Casualties with comparable wounds were divided into two groups in forward surgical units. Except for the drugs employed these men were all treated alike, but one group received only the routine prophylactic doses of parenteral and/or local penicillin, while men in the other group were given both penicillin and sulphonamides. The wounds of these patients were carefully compared when they were first examined in base hospitals. In the assessment of infection four categories were used: 0 (none), + (slight), ++ (moderate), and +++ (severe). The results compiled from the reports of 17 surgeons are given in Table II.

TABLE II

Agents	Total Cases	Degree of Infection				Percentage 0 and +
		0	+	++	+++	
Penicillin only (parenteral and/or local)	497	298	165	28	6	93.1
Penicillin (parenteral and/or local) plus oral sulphonamides	480	275	159	37	9	90.4
Sulphonamides only (oral and usually local)	157	74	41	25	17	73.2
Totals	1,134	647	365	90	32	88.8

The number of severe infections was highest in the 'sulphonamide only' group, but most of these were in prisoner patients, and it would be misleading to compare them directly with the others. Study of the other groups shows that the men who received penicillin only did not suffer from the absence of a sulphonamide. Although the difference between the results is small, it is significant that a higher proportion of the men in the 'penicillin only' group received parenteral penicillin, suggesting (a surmise confirmed by personal investigations) that this group contained a higher proportion of men with severe wounds, these being the ones more likely to receive parenteral penicillin. Thus the interesting fact emerges that in this series of about 1,000 cases the men with the severer wounds received more prophylactic parenteral penicillin and had less infection. The moral of this and similar observations in many other cases is obvious: in order to secure maximum protection for those with severe open injuries penicillin should be used *both* parenterally and locally.

Anaerobic Myositis—The value of penicillin in prophylaxis, and possibly in therapy, is further confirmed by studying the figures for anaerobic myositis. The high incidence of this serious infection in the war of 1914-18 and in the disastrous struggle in 1940 gave rise to inevitable fears of a similar high rate when fighting was renewed over the same ground. The penicillin memorandum issued for the guidance of medical officers just before the invasion of Normandy in 1944 drew particular attention to the 'gas-gangrene prone' type of case and placed these patients in the highest priority for penicillin prophylaxis. The recommendations were interpreted generously, and the rate of penicillin expenditure was high, but the policy was justified by the results. In the desert campaigns MacLennan (1944) calculated that the incidence of gas-gangrene was 3.4 per 1,000 and in Tunisia 6.7 per 1,000. Jeffrey and Thomson (1944) estimated that the rate in Italy was not less than 10 per 1,000. It is unknown whether the above figures include cases among prisoners. In NW Europe the incidence in Allied troops (Porrirt and Mitchell 1945) was 1.5 per 1,000, and, although no exact figures are available, it was very much higher in enemy troops. Incidentally, it is worth noting that sulphonamides were used freely by the Germans both in prophylaxis and in therapy. The death rate in cases in NW Europe was also exceptionally favourable, being 21.5% in Allied troops—the lowest recorded mortality in any large series of cases. The actual figures for the entire campaign in NW Europe are given in Table III.

TABLE III—*Anaerobic Myositis Cases treated by 21 Army Group Surgeons D Day (June 6 1944) to V E Day (May 8 1945)*

Categories	Cases	Deaths	Percentage Mortality
Allied troops	251	53	21.5
Prisoners	113	59	45.1

The existence of many variables in wounds sustained and treated in the field renders the exact assessment of their individual importance difficult or impossible. But the one really new factor in the NW European campaigns was the widespread prophylactic use of penicillin both parenterally and locally, and in any reckoning it must be accorded a good deal of the credit for the diminished incidence and improved results.

I have deliberately focused attention upon the prophylactic value of penicillin because to date its therapeutic applications have secured almost all the publicity. Penicillin may produce brilliant results when established and hitherto moribund cases but it would be a better bet for the patient if less emphasis is placed on preventing infections or modifying their course. Here lies the greater promise of

penicillin in surgery—to abolish or reduce the incidence and severity of pyogenic and anaerobic infections by the judicious combination of surgery and penicillin.

Prophylactic Administration—In minor wounds local applications are usually adequate. The wound should be dusted with penicillin powder at the first examination, and this procedure may be repeated if necessary, but unnecessary dressings or interference should be avoided. In war wounds we used 5,000 Oxford units of penicillin per gramme, the diluent being sulphonamides or powdered plasma. For the average civilian case, which is treated sooner and is less heavily contaminated, a smaller concentration of penicillin should be adequate. In more severe wounds, particularly in those with much tissue damage, associated vascular lesions, retained foreign bodies, or open bone and joint injuries, penicillin should be used *both* parenterally and locally as soon as practicable after the accident—e.g., on admission to the casualty department of a hospital. For prophylaxis intermittent injections are most often used, and, depending on circumstances, dosages between 15,000 and 100,000 units per injection have been employed, the smaller doses are given three-hourly and the larger every five to six hours. The lower dosages should be sufficient in civilian practice. With the increasing availability of penicillin in slow-release vehicles, such as the oil and beeswax suspensions, these may be employed to reduce the number of injections and give more prolonged protection, they have the disadvantage that they are difficult to inject. Reliable and economical oral methods of administration have not yet been perfected. When they are they will become the method of choice except in those patients who have been exposed to great infective hazards or who show evidence of developing a fulminating infection. If the patient is admitted to hospital continuous methods of administration may be instituted from the start and the prophylactic administration may then merge into the therapeutic, the average daily dosage by this method is 100,000 to 120,000 units, and most practitioners will be familiar with the various forms of apparatus that may be employed.

Penicillin administration should be started at the first available opportunity and should be continued until the satisfactory state of the patient's local and general conditions shows that the danger of infection is past.

In patients with heavily contaminated wounds the initial prophylactic dose may be boosted up to 100,000 units, or, if continuous methods of administration are employed, 300,000 units may be given during the first 24 hours. The larger doses are specially indicated if there has been any delay in instituting treatment or if there are associated vascular lesions. The higher blood titre thereby obtained may produce an adequate penicillin level in partially devitalized or devascularized tissues but it is re-emphasized that surgery is still the main bulwark in these cases both in prevention and treatment. Unless there is some specific indication for their use, prophylactic sulphonamides may be withheld if penicillin is being administered.

Value of Penicillin in Therapy

An enormous volume of evidence has been published regarding the therapeutic value of penicillin in a wide variety of conditions. This being so, there is no need to add wood to the pile of well-established facts, and in any case one could not even summarize all the evidence within an hour. It will be more profitable to discuss an experiment (21 Army Group Memo, 1944) which was carried out by Army surgeons in an attempt to discover the relative value of different agents in eliminating or controlling wound infection. Surgeons were asked to treat alternate cases

(a) with penicillin and (b) with a contrast agent. To avoid complicating the issue, casualties with associated visceral, bony, or articular injuries were excluded. Apart from this, patients treated were consecutive and unselected, and they had wounds of the soft tissues of all grades of severity. The idea was that each surgeon would choose what he regarded as the best alternative to penicillin, and it was emphasized that, apart from the chemotherapeutic agent employed, every other controllable factor, such as surgery, diet, rest, etc., should be of equal quality, with no preferential treatment for any case.

Before describing the results it may be of interest to explain why this investigation was initiated. In the earlier stages of the war surgeons were frustrated by the prevalence of sepsis, and they soon discovered that secondary sutures, grafts, and plastic procedures, however desirable in theory, were not safe in practice. Despite various attempts to evolve improved methods of treatment this state of affairs persisted substantially unchanged until the pioneer work of Florey and Cairns (1943) and their collaborators showed in N. Africa that many wounds could be closed safely under the protective mantle of penicillin. By the time of the invasion of Normandy the much greater supplies of penicillin available permitted its widespread employment as a prophylactic agent. As a result at least 9 out of 10 wounds were clinically clean when they were first examined at base hospital level, and secondary closures became the commonest operations performed. They were carried out regularly and with impunity not only on clean wounds but on many which, in pre-penicillin days, would have been regarded as quite unsuitable for suture. This notable advance conferred untold benefits in the prevention of pain, in providing better functional and cosmetic results, in avoiding prolonged suppuration with consequent visceral damage, and in shortening convalescence. As Porritt, Debenham, and Ross (1945) commented: "The results achieved led to a saving of man-power, a reduction in wound complications, and an economy in hospitalization, in supplies of drugs and equipment, in surgeons' and nurses' time which it is quite impossible either to compute or to appreciate fully."

All this is now generally known, but when the medical plans were being made for the invasion of Normandy penicillin was merely a name to most surgeons. Preliminary reports about it were very encouraging, but many surgeons held that the case in its favour was unproved, since the earliest casualties treated had received preferential treatment—e.g., they had been retained in forward hospitals for longer periods than comparable casualties not treated with penicillin, and they had benefited from unusually specialized medical attention. It was therefore decided that the relative value of penicillin could not be assessed accurately until it was tried out on absolutely equal terms against other popular agents. This was the background behind the decision to initiate the investigation mentioned above.

The results proved the superiority of penicillin beyond reasonable doubt as Tables IV and V reveal.

TABLE IV—Results of Wound Sutures in 4432 Cases

Agents Used	Total Cases	Grade I		Grade II		Grade III		Percentage Grades I and II
		No.	%	No.	%	No.	%	
Penicillin local applications only	2 359	1 881	79.73	348	14.75	130	5.52	94.48
Penicillin local and parenteral	1 485	1,221	82.22	185	12.46	79	5.32	94.68
Penicillin, parenteral only	107	92	85.98	12	11.21	3	2.81	97.19
Sulphonamides local and systemic	141	88	62.41	30	21.27	23	16.32	83.68
Sulphathiazole-proflavine mixtures—local	183	99	54.09	51	27.88	33	18.03	81.97
Nil	157	114	72.61	25	15.92	18	11.47	88.53

The results may be shown more simply by contrasting the penicillin cases with all the others.

TABLE V

Agents Used	Total Cases	Grade I		Grade II		Grade III		Percentage Grades I and II
		No.	%	No.	%	No.	%	
Penicillin	3 951	3 194	80.84	545	13.79	212	5.37	94.63
Others	481	301	62.57	106	22.04	74	15.39	84.61

The wounds were assessed on a uniform standard.

Grade I (Success)—Wound healed and completely dry at the end of 14 days. This period was selected as sutures were often performed under some tension and then the stitches were not removed until the eleventh or twelfth day.

Grade II (Partial Success)—Wound incompletely healed at the end of 14 days (slight moistness, small gaps, mild stitch suppuration, etc.), but healed and completely dry at the end of 21 days.

Grade III (Failure)—Wound incompletely healed at the end of 21 days.

Anyone with experience would regard Grades I and II as successes for the delayed suture of war wounds, so both were included when computing the percentages in the final column. As originally planned the investigation should have provided results in almost equal groups of cases. In fact, they were unequal, and the reason was simple. Most surgeons became so impressed at a relatively early stage by the superiority of penicillin that, for the sake of the wounded, they abandoned the use of contrast agents. Despite this a clear answer was obtained to the problem under investigation. In this large series of cases treated by many different surgeons penicillin proved itself superior to all other agents tested. This result is more evident if the highest standard (Grade I) is regarded as the criterion of success, and the superiority of penicillin over the other agents becomes less evident if the standard is lowered and both Grades I and II are regarded as successes.

The results in the group of patients whose wounds were sutured without any adjuvant agent are interesting, but they cannot be compared strictly with the others as this group contained only minor cases. It represents what can be accomplished by unaided surgery in small clean wounds and it must be remembered that the wounds were clean when the patients reached hospital, because the men had probably received prophylactic penicillin in some forward surgical unit. On the other hand, the penicillin groups—and particularly those treated with parenteral penicillin—contained almost all the major wounds, yet these showed the highest standard of success. In the light of this knowledge the penicillin results appear to be still better.

Analyses of other features connected with these cases supplied the same answer—that penicillin had no serious rival—and, if time and space permitted, figures could be quoted relating to other injuries and diseases which all support the belief that penicillin is of supreme value. Time and space, however, are finite in medical if not in mathematical affairs, and perhaps the facts and figures I have given, together with those already known to you, will strengthen your belief that Fleming, by an inspired vision discovered what had seemed until then a biological impossibility—the almost perfect antiseptic.

A REVIEW OF THE DIETETIC FACTORS IN LIVER DISEASE

BY

L. J. WITTS, MD, F.R.C.P.

Witfield Professor of Clinical Medicine University of Oxford

II—THE APPLICATION OF NUTRITIONAL PRINCIPLES IN TREATMENT*

Acute Necrosis of the Liver

Acute necrosis of the liver is an anatomical diagnosis which cannot be made with certainty without biopsy or necropsy. Usually, however, we must rely on the indirect evidence of acute hepatic insufficiency. Jaundice is intense and the serum bilirubin rises to 20 mg per 100 ml or higher. The patient is critically ill with delirium, stupor, coma, and up-going toes. There are ascites, oedema, purpura, and occult blood in the stools. If we confine the terms "acute necrosis" and "acute hepatic insufficiency" to such cases—and I believe we shall make no therapeutic advance until we establish rigid criteria—we shall find ourselves dealing with a hepatic disorder which is uncommon and which has a mortality of 50 to 100%. From a sample analysis of death certificates carried out for the Jaundice Committee of the Medical Research Council by Dr W. H. Bradley and Dr Percy Stocks in 1944 (unpublished report), it appeared that there were approximately 400 deaths a year from acute hepatic insufficiency, of which only about 8% were toxic jaundice, whereas the greater part were probably due to the viruses of infective hepatitis, homologous serum jaundice, and post-arsphenamine jaundice. The average number of deaths from notifiable toxic jaundice during the years 1940–4 was fewer than six a year. I stress the rarity of fatal toxic jaundice in man in view of the fact that so much of our present information has been derived from toxic jaundice in animals.

The difficulties of carrying out therapeutic trials on a disease which is uncommon and hard to diagnose are great. Much of the literature on the subject is worthless, recording isolated successes, changes of fashion, and the surprising capacity of the organism, even in sickness, to withstand onslaughts on its integrity. This state of things should improve as a result of the careful collection and study of morbidity and mortality statistics which is occurring in several parts of this country. More is to be hoped from animal experiments, which are still curiously incomplete in the matter of treatment. The drawbacks to animal experiment are the dissimilarity of animals and man, and the failure to transmit infective hepatitis to animals. Another possibility, which it is to be hoped we shall be spared, is the occurrence of epidemics of infective hepatitis with a mortality of the order of 15%, such as have lately appeared in Denmark and Switzerland.

* The second of two University of London Lectures in Medicine given at the Westminster Hospital Medical School on Oct. 29, 1946. The first lecture appeared in last week's issue.

It will be simplest to begin by discussing orthodox therapy with glucose. The untreated hepatectomized animal always dies of hypoglycaemia, and life may be prolonged for many hours by the administration of glucose. Dextrose therapy in diseases of the liver in man has been reviewed by Althausen (1933), but perhaps the most convincing data are those of Chester Jones (1936). He collected 56 cases of acute hepatic insufficiency from the records of the Massachusetts General Hospital and showed that the mortality had fallen from 95 to 63% over a period during which glucose therapy had been made more intensive. In the final period an attempt had been made to give the patient 450 to 500 g of carbohydrate by mouth, usually combined with intravenous therapy, with solutions of glucose ranging from 5 to 25%.

There is no magic in glucose, whether it is given by mouth or intravenously, but there are, nevertheless, circumstances in which the intravenous injection of glucose may be of special value. There is normally a careful adjustment between the level of blood sugar and the release of sugar into the circulation by the liver. When the liver is damaged it may require a much higher concentration of blood sugar than normal to inhibit the formation of hepatic sugar. Such levels may not be attainable by oral feeding, and the intravenous infusion of dextrose may be essential. The fact that the hyperglycaemia so produced may lead to glycosuria is of no moment, and insulin should not be used as a rule or it will defeat the very purpose for which the glucose was given (Soskin and Hyman, 1939). A small number of human cases of acute hepatitis was treated by Minot and Cutler (1929) on a meat-free diet rich in carbohydrate, accompanied by oral administration of calcium lactate, but the work does not seem to have gone very far. Nevertheless it has become standard practice in acute hepatic insufficiency to administer calcium intravenously, usually in the form of 10 ml of 10% calcium gluconate, though few who carry out this procedure have read Lamson's (1930) advice on the need for extreme care and slowness.

The remarkable success of a high intake of certain proteins and protein derivatives in the prevention of acute necrosis in animals and in the treatment of cirrhosis in man has naturally given rise to the hope that these substances might be of value in acute hepatic insufficiency. Many theoretical objections can be raised against this new heterodoxy. The metabolism of proteins and amino-acids demands work from the liver, and it is a cardinal principle of therapeutics to rest a damaged organ. There is abundant evidence that meat and meat extracts may be positively harmful to animals with acute or repeated damage to the liver from carbon tetrachloride. The patient with acute hepatic insufficiency is liable to extrarenal azotaemia and uraemia, though opinion is divided whether this should indicate or contraindicate the administration of protein (Leitus, 1946; Zondek, 1946). In some cases of severe damage to the liver a state of acute renal failure develops which is known as the hepato-renal syndrome and which has been attributed to toxic derivatives of protein (Helwig and Schutz, 1932; Reich, 1941; Trueta *et al.*, 1946).

In this atmosphere of doubt the ordinary clinician will do well, in the treatment of acute hepatic insufficiency, to concentrate on the relief of shock and the restoration of the normal internal milieu of the organism by fluids and glucose. Milk protein appears to be harmless and milk should therefore form part of the fluid intake, though it is unlikely that more than 30 to 40 g of protein will be supplied in this way. The therapeutic value and application of nitrogenous materials such as choline, amino-acids, protein hydrolysates, and plasma still await demonstration in

animal experiments and in controlled trials in man, and are the province of the research worker. No one knows yet whether they are helpful or harmful.

It would nevertheless be cowardly to leave the subject here without reviewing such data as are available. It is true that there is no evidence, even in animals, that proteins or amino-acids influence hepatic necrosis favourably once it has been established, though there is good evidence that choline accelerates recovery from fatty change. On the other side of the slate the research worker would note that 90% of deaths from infective hepatitis occur relatively late, when the disease has lasted more than 20 days (Lucké, 1944). The necrosis of experimental carbon tetrachloride poisoning may be repeatedly repaired, perhaps up to 40 times, but in the end there is a final phase of exhaustion when the rat is no longer able to restore the liver to normal (Cameron and Karunaratne, 1936). This suggests that patients with necrosis may run out of critical materials for regeneration of liver tissue. Regenerative ability doubtless varies from individual to individual owing to differences in hereditary and acquired characteristics, of which the previous state of nutrition is the most obvious. Death in acute necrosis may therefore be due either to temporary hepatic insufficiency or to exhaustion of the recuperative power. In our orthodox treatment we concentrate on tiding the patient over the period of hepatic insufficiency. In the future we may learn to fortify the recuperative power.

Acute Infective Hepatitis

Far and away the commonest disease of the liver in this country is infective hepatitis, or catarrhal jaundice. During the war acute hepatitis was made notifiable in Region IV, which had a population of over two and a half millions. Notification has been in force over two complete years, 1944 and 1945. The number of cases decreased from 3,559 in 1944 to 1,626 in 1945, and the incidence rate fell from 1.3 per 1,000 to 0.6 per 1,000. Voluntary notifications showed that the incidence had been higher in 1943 than in 1944. Practically all the cases notified were acute infective hepatitis. From these and other data we can assume that there were somewhere between 25,000 and 50,000 cases of infective hepatitis a year in Great Britain during the war. The mortality of infective hepatitis is about 0.2 to 0.4%, that of homologous serum jaundice and post-arsphenamine jaundice is probably higher. Owing to its low mortality and its prevalence in children, infective hepatitis is not usually regarded very seriously. During the war, however, epidemics occurred amongst our troops overseas which came near to disabling whole armies and air forces. Moreover, there was a high incidence of homologous serum jaundice and post-arsenical jaundice. These last two forms of jaundice are due to a virus which is similar to but probably not identical with the virus of infective hepatitis, and I shall consider the treatment of all three without discriminating between them.

The therapeutic problem in infective hepatitis is not mortality but the long period of disability, which averages 40 days. Various experiments have been carried out with diets and dietary principles, but no specific effect on the disease has been discovered. There is a general impression that strict rest is more important than strict diet. All that has been done—and this is undoubtedly gain—is to prevent patients being made miserable or unwell by unnecessary dietetic restrictions. Two observations can be offered in partial explanation of the failure of dietetic therapy in infective hepatitis. The main onslaught of the disease has usually occurred by the time the patient comes under treatment, and it is unusual to encounter the metabolic disturbances which arise in severe injuries and infections.

Pollock (1945) has shown that bromsulphthalein retention, biliruria, and a qualitative change in serum bilirubin may be present in the pre-icteric stage of infective hepatitis several days before the onset of jaundice. There is also a pre-icteric rise in phosphatase (Higgins and O'Brien, 1946). The earliest biopsies show gross changes in the liver, and Dible, McMichael, and Sherlock (1943), in their account of aspiration biopsy studies, say that the liver inflammation probably begins with the prodromal symptoms which are so often regarded as gastro-intestinal in origin. With the onset of clinical jaundice all the functions of the liver are found to be disturbed—carbohydrate metabolism, biliary excretion, hippuric acid and protein synthesis. Recovery usually occurs in the sequence of falling bilirubin, recovery of carbohydrate metabolism, normal hippuric acid excretion, normal level of albumin and globulin. I have already described carbohydrate as the great source of energy for the metabolic activities of the liver, and the impairment of carbohydrate metabolism, coupled with the restricted food intake, may be the cardinal event in the general depression of liver function.

Interest has recently been revived in the great loss of nitrogen which sometimes occurs in acute illnesses and after operations, accidents, and burns (Cuthbertson, 1944). The reason for this nitrogen loss, which reaches its maximum about the middle of the second week after the incident, is not known. It is not mere shortage of calories, and there is a suggestion that body protein is broken down to supply scarce substances for repair. Not only is weight lost during this phase but the healing of wounds, burns, and fractures may be retarded. Peters and his group (Peters, 1945) have made a particularly interesting study of the biochemical lesion in experimental burns. They found that there were heavy losses of nitrogen on the basal diet which could be largely prevented by a high-protein diet. They suggested that the losses were due to the raiding of tissue stores of nitrogen for one or more essential amino-acids, and showed that these could be prevented by the addition of 1% methionine to the basal diet, but not by cystine. The administration of high-protein, high-calorie diets has been recommended for general use for human convalescents (Stevenson, Whittaker, and Kark, 1946), and it is natural that similar diets should have been specifically recommended for infective hepatitis, where there is considerable cellular damage to the liver.

We have found no evidence of toxic destruction of protein in infective hepatitis. My colleagues Higgins and O'Brien (1946) found a negative nitrogen balance in three out of six of our patients, but in only one was it serious; the other three patients were in positive balance. The patients were studied as early as practicable, and it is unlikely that a negative phase was missed. Creatinuria, though frequent, was variable in degree and capricious in appearance. The evidence suggests that only occasionally is there a serious nitrogen imbalance in infective hepatitis, and in the majority of cases the negative balance which is apparent in the early stages is a reflection of the duration of the nausea rather than the severity of the hepatitis as judged by the bilirubinaemia. Similar rather negative conclusions were drawn by Higgins and O'Brien from a study of the plasma proteins in our patients. All the patients with serum bilirubin over 5 mg per 100 ml showed a slight to moderate fall in serum albumin and a slight rise in globulin. In cases followed from the pre-icteric stage the first event was the fall in plasma albumin. Albumin quickly returns to normal when the bilirubinaemia declines, but globulin may be much slower. The fall in serum albumin is certainly not entirely due to nausea, for it continued in patients who ate well and had a high protein intake, and in others who

had additional amino-acid therapy. It is probably related to a failure of manufacture of plasma proteins due to impairment of the liver and not to a shortage of raw materials.

The technique of therapeutic trials in infective hepatitis is now more or less standardized. We cannot use the death rate, and must rely on the duration of illness, the occurrence of relapses, and the frequency of permanent damage. The disease varies greatly in severity, but satisfactory criteria can be established for duration of biliuria, anorexia, hepatic enlargement, etc., comparability of cases, and the requisite number of cases and controls. Using such a technique Darmady (1945) found no difference between a high-calorie, high-protein, high-vitamin diet and a classical low-fat diet. Hardwick (1945) found no difference in patients allowed 180 and 50 g of protein a day. Wilson, Pollock, and Harris (1946) found no difference in groups of patients on 202 and 68 g of fat a day.

Results with dietary supplements are likewise disappointing. Higgins *et al* (1945) and Wilson, Pollock, and Harris (1945) observed no effect from methionine, 5 g a day by mouth, and Hoagland and Shank (1946) were equally unsuccessful with methionine, 5 g a day intravenously. Rennie (personal communication, 1945) had no success with cysteine, 15 g a day by mouth. On the other hand Peters and his co-workers (Peters, Thompson, *et al*, 1945) observed significant improvement of results with cysteine, 2 g daily by mouth, and with methionine, 2.5 to 5 g daily by mouth, and Wilson, Pollock, and Harris (1946) observed significant improvement with cysteine, 5 g daily by mouth. The latter group of workers noted that the improved figures were largely explained by a smaller number of exacerbations or relapses in the treated series, and in both series the difference between the treated cases and the controls was not great. Viswanathan (1945) claimed improvement from intravenous injections of protein hydrolysate. Richardson and Suffern (1945) and Hoagland and Shank (1946) had no success with choline, 1.5 to 5.0 g daily by mouth. Lenz (1944) had no success with insulin and glucose, and Gordon (1944) none with insulin, glucose, and vitamin C. Hoagland and Shank (1946) also had no success with intravenous liver extract.

These therapeutic trials have not escaped criticism. The diets which were being compared were not always isocaloric, but that is chiefly because a low-fat diet is unappetizing. It is objected that the intake of protein was so low that the methionine or cysteine could do little more than compensate for this. Protein intakes in our patients varied at different times from 34 to 120 g a day, with an average of 80 to 90 g. The high-protein diets used in jaundice are not very high in comparison with the 300 g a day forced in by Taylor (1944), but anything more than 150 g a day is a *tour de force*. Finally it is calculated that the curative dose in man would be 20 g of choline a day for two or three weeks, or 20 to 60 g of methionine (Barclay *et al*, 1945). Such large amounts are impracticable of ingestion and would require intravenous administration. This technique would be justifiable as part of a planned research on the treatment of acute necrosis of the liver, but surely not for so benign and common a disease as infective hepatitis.

My practical advice (Witts, 1945) on the treatment of infective hepatitis is that neither the fat nor the protein should be too low. A low-fat diet is unappetizing and commonly implies undernutrition. A very low protein diet is undesirable in a patient who has to regenerate shattered columns of liver cells. "Clinical experience has confirmed Bollmann's (1943) conclusions from the treatment of animals whose livers had been damaged by carbon tetrachloride

that 'the caloric value of the diet should be as high as possible, and the ratio of carbohydrate and protein in the diet seems to be of less importance than the total caloric intake furnished by these substances. The basic rule in the treatment of acute hepatitis is that the intake of fluid and food should be adequate to protect the patient from dehydration, acidosis, and tissue breakdown from malnutrition. The damaged liver is coping simultaneously with two tasks—the day-to-day needs of metabolism and the repair of its own substance—and it must be neither starved nor overburdened with material. A light diet with plenty of milk from which the top layer of cream has been removed fills the bill admirably. Self-selected diets also work out well, and it seems the patient will take no harm if he eats what he likes, whether he behaves like Jack Spratt or his wife. The real problem is when he does not want to eat at all. Turner *et al* (1944) believe that if the patient were given an infusion of dextrose for every meal avoided or vomited some disasters might be obviated."

Treatment of Cirrhosis

Cirrhosis of the liver is not a common disease in Great Britain, for the number of deaths from this cause has fallen below 1,000 a year. The average duration of life of our Oxford patients is about two years after coming under treatment, so that the total number of cases being treated in the country at any one time is probably about 2,000. The small number of cases makes it difficult to carry out therapeutic trials, for in a chronic disease like cirrhosis the results are best assessed by the determination of survival rates, one year, two years, three years, etc., after the patients come under observation, and this technique necessitates a large number of cases. Moreover, we ought, if possible, to distinguish between alcoholic and non-alcoholic cases, between portal cirrhosis and postnecrotic fibrosis, and this is not always easy, even after post-mortem examination. British figures are not comparable with American figures owing to the much lower incidence of alcoholism in this country. Dr A. R. Kelsall (personal communication, 1946) has reviewed the 48 cases of cirrhosis which have been admitted to the Radcliffe Infirmary in the last six years, and not more than two could be attributed to alcohol. The non-alcoholic cirrhoses have a closer affinity with postnecrotic fibrosis than with fatty infiltration or portal cirrhosis, and their course is more protracted and variable than that of alcoholic cirrhosis.

The changing character of cirrhosis of the liver must be borne in mind when we use past experience, such as the excellent data of Ratnoff and Patek (1942), to assess the value of new therapeutic procedures. These authors have also provided figures for the usual length of survival after the onset of ascites, jaundice, or haematemesis. There is great variability, and a small number of patients survive five years or more after these alarming symptoms. The chief desideratum, therefore, in any experiment on the treatment of cirrhosis is a large and unbiased sample of cases, which can be divided into treated and control groups and from which results of statistical significance can be deduced. In the study of individuals, chemical observations on the blood, in particular the level of serum proteins, afford objective evidence of the course of events.

Hurst (1946) has written of a precirrhotic condition of the liver, and on theoretical grounds we should expect fatty infiltration to do better than cirrhosis, but this can hardly be diagnosed clinically without biopsy. A fatty liver may be expected to be a large liver, but it is all too easy to confuse a large liver with a hard liver, and the determination of the size of the liver is a more difficult feat than many people have realized. Ravdin and co-workers (1943) proved by

biopsy that approximately 30% of patients with long-standing gall-stone disease had abnormally large amounts of lipid present in the liver, and they showed that this could be reduced by a diet of 74% carbohydrate, 20% protein, and 6% fat, in which bananas and casein figured prominently

It has long been taught that milk is the ideal diet for cirrhosis (Rolleston and McNee, 1929). Beginning with this observation, we may omit description of the groping advance through regimens of low fat, high carbohydrate, adequate calories and vitamins, and high protein, and skip at one bound to the impressive studies of Morison (1946). Morison treated three groups of cases of cirrhosis. There were about 20 patients in each group, and about half of each group had ascites. The first group was given a high-carbohydrate diet and diuretics. The second group was given a high carbohydrate high protein diet, liver extract, and vitamins. The third group had a maximum intake of protein, liver extract, and vitamins, plus methionine and choline, of each 2 g daily. In patients without ascites the intensive combined treatment in the third group resulted in the remission of all signs and symptoms in 7 out of 11, as compared with 1 out of 11 in the first (control) group. In patients with ascites complete remission occurred in 4 out of 9 of the third group, as compared with 0 out of 12 in the first. The death rate was very greatly reduced in the third group. The second group occupied an intermediate position. Morison's maximum protein regimen comprised a diet of 2,500 to 4,000 calories with 200 to 300 g of protein, 300 to 500 g of carbohydrate, and 50 to 100 g of fat, and included 6 glasses of skim-milk a day.

Other workers have given much less protein than Morison, and they have not obtained such dramatic results, though their figures have shown an improvement on the past. Fleming and Snell (1942) found that among 150 patients treated with a high-carbohydrate and low-protein diet plus diuretics, they had good results in 30%, whereas among 50 patients treated with a diet including 350 to 500 g of carbohydrate, 110 g of protein, chiefly in the form of milk and vegetable protein, plus vitamin supplements, the results were good in 44%. Beams (1946) treated 20 patients on a regimen similar to Morison's second group, giving them in addition 30 to 45 g of brewer's yeast, and choline and cystine, of each 1.5 to 3 g a day. He found that 12 of the 20 patients whose livers were not enlarged gave no response, whereas 7 of the 8 who had large livers made a good recovery. Patek and Post (1941), in a statistical study which should be a model to later workers, gave a regimen similar to Morison's second group—i.e., 120 to 140 g of protein, without thio-amino-acids or choline—and presented convincing evidence of improvement over previous treatment with high-carbohydrate and lower protein diet. Homburger (1946) studied carefully a patient who had been stabilized on a high-protein regimen. He produced evidence that substitution of the protein by an isocaloric amount of carbohydrate was attended by deterioration of the clinical and biochemical state.

In view of the many factors employed it has not been possible to isolate the effects of choline and methionine. Small series of cases treated with methionine with apparent benefit have been reported by Broun and Muether (1942), Herrmann and Rockwell (1945), and Russakoff and Blumberg (1944), the last giving up to 6 g a day. On the other hand, Man and co-workers (1945) gave choline in large doses, 10 to 25 g a day, to three patients with cirrhosis without demonstrable effect. Echaurren and Jorquera (1943) found the daily administration of 600 mg of inositol helpful.

I will conclude with an account of our own efforts in the treatment of subacute and chronic hepatitis. Of the 48 cases admitted to the Radcliffe Infirmary in the last six years, 35 provided records suitable for analysis. Twenty-two of the patients were treated with high-protein diets, combined in most cases with a high carbohydrate and low fat intake and often supplemented by vitamin A and D concentrates, synthetic vitamin K, and food yeast. Protein intakes averaged 125 g a day, but were supplemented by 30 to 60 g of food yeast over long periods. No methionine was used, and a very small number received choline or protein hydrolysate, and then only for short periods. Thirteen patients received the classical treatment with relatively low protein diets and diuretics. The numbers are small, but there is no significant difference between the two groups, whether one compares the mortality, as in the following table, or the average duration of life in the various subdivisions. The results of dietary treatment in non-alcoholic cirrhosis are therefore discouraging.

	Alive	Dead	Total
Treated	15	7	22
Untreated	8	5	13
	23	12	35

Discussion

Disorders of the liver similar to those produced in experimental animals by dietary deficiency occur in man over wide territories of the world as a result of inadequate food supplies. The incidence of juvenile cirrhosis and primary carcinoma of the liver may well come to be regarded as indexes of nutrition. The problem must now be attacked by social engineering rather than medical science. It is merely one symptom of world pressure on food supplies, and it will not be solved by bread alone but by a completely different way of life among crowded people with high birth rates. The number of isolated dietary defects which are known to produce disease is already great, but we are still learning the simple arithmetic of nutrition and are not yet able to permute and combine the various factors so as to discover how they reinforce or neutralize one another. In the relatively simple problem of blood formation we are just beginning to realize how iron requirements may be affected by the protein and vitamin content of the diet. It therefore seems unlikely that fortification with individual principles will be as cheap or as effective as a general improvement of the diet in the prevention of hepatic diseases. Our knowledge is more likely to be useful in the selection of those natural foods which can be most expeditiously used to increase the biological value of the diet.

It is too early to assess the value of the new knowledge in the treatment of hepatic disease in the better-nourished populations of the world. Among them infective hepatitis and allied virus infections vastly predominate over all other forms of disease of the liver, and advances are more likely to come from bacteriology than from the science of nutrition. Alcoholism is a symptom of prosperity rather than austerity, and can be overcome only by a general improvement in the art of living. Nevertheless, we can still hope that appreciation of the nutritional requirements of the hepatic cell, and of the body as a whole, will enable us to improve the chances of recovery in the acute phases of hepatitis and to accelerate regeneration and repair at a later stage.

SURGICAL ASPECTS OF ROUNDWORM DISEASE

BY

F BARBER, M.R.C.S.
Cap an R.A.M.C.

During my last two years as surgeon to the native population of Cyrenaica I repeatedly came across roundworm infestation either simulating surgical conditions or indicating, and in my opinion justifying surgical intervention. The following three case reports illustrate these points.

Case 1

A boy aged 13 was seized by spasmodic abdominal pains and violent vomiting while at school on Dec 12, 1945. He was brought to hospital about an hour after the onset of symptoms. Inquiry revealed that he had been suffering from similar attacks of less intensity for the last ten months. They used to come on about twice weekly at odd times, his pain apparently being localized in the epigastric region. For the same period he had shown no appetite and had been constipated.

Examination showed a thin, very pale boy. The temperature was normal, pulse 100 weak. The tongue was coated and moist. Chest N.A.D. The abdomen was not distended, its excursions on respiration were noticeably restricted, and it was very tender with rigidity especially in the right iliac fossa. Per rectum the pouch of Douglas was slightly tender, but no effusion was palpable. An acute appendicular attack with peritoneal irritation was assumed. Following resuscitation, the patient's general condition improved and operation under open ether anaesthesia, was performed about four hours after admission.

A right pararectal incision was made. The abdominal cavity contained much turbid fluid but no pus. Coils of small intestine presented, thronged with roundworms. The caecum was found above the level of the umbilicus. The appendix was in the retro-caecal position, and not adherent. Its tip was swollen and covered with a pink serosa. After appendicectomy the presenting loop of ileum, which was crammed with worms, was opened, and the worms (*Ascaris lumbricoides*) were removed. Masses of worms contained in other parts of the small gut were 'milked' towards the opening and taken out. The longitudinal opening of the bowel wall was closed transversely, a rubber drain was inserted into the pouch of Douglas, and the abdominal wound was sutured. Altogether 91 worms were removed. The appendix contained a fecalith the size of a cherry stone. The mucous membrane underneath was blackened with ulceration, which however macroscopically did not involve the deeper contents. The post-operative course was uneventful but the patient now and again complained of abdominal spasms. Following a course of anthelmintic treatment two weeks after operation several more worms were passed. There has been no abdominal discomfort since, and he was discharged cured.

Case 2

A little girl aged 5 was admitted to hospital on May 2, 1946, having been sent by her physician, who diagnosed appendicitis. She had had abdominal pains and retching for the preceding two days. The bowels were normal. The mother stated that she had never noticed worms in the child's stools. The temperature was 99.5° F (37.5° C), pulse 90. The general condition was fair. Chest, N.A.D. The abdomen was moderately distended, with tenderness and slight rigidity in the right iliac fossa. On deeper palpation intestinal coils containing longitudinal masses, like bundles of pencils, and very suggestive of roundworms, could be felt through the thin abdominal wall. Santonin and castor oil were given on three subsequent days. Masses of ascarides were passed in several motions. Immediately after treatment the abdominal pains disappeared and the temperature fell to normal. The patient was discharged cured on May 10.

Case 3

A male child aged 3 was admitted to hospital on May 27, 1946 Two days before admission he had had abdominal pains and vomiting and his last bowel motions occurred three days previously The temperature was 101° F (38.3° C), pulse 100 regular The general condition was fair He had abdominal facies, the tongue was coated and respirations were of the thoracic type The abdomen was distended, diffusely very tender, with rigidity especially in the right iliac fossa There was free fluid on percussion Per rectum there was no appreciable disease On the assumption of an inflammatory intestinal condition involving the peritoneum, possibly of appendicular origin, laparotomy was performed under general open-ether anaesthesia

A right pararectal incision was made, and a fair amount of heavily blood stained turbid fluid of slightly faeculent odour was found on opening the abdominal cavity The caecum and appendix did not show any abnormality A loop of ileum belonging to the middle portion of that gut was found to be distended and intensely red, its wall was thickened with inflammatory infiltration, and on the serous surface a thread like whitish network of swollen lymph vessels was visible The loop involved measured about 18 in (45 cm), a kink forming a double barrel shaped incomplete intestinal obstruction about 1/2 in (1.25 cm) long The wedge of mesentery belonging to it was grossly thickened to approximately 1/3 in (0.8 cm) in diameter and appeared white with fibrinous purulent infiltration The mesenteric glands were swollen to the size of a cherry or walnut A mass of partly curled up worms was palpable in the diseased gut and there was worm infestation of less intensity in other sectors of the small intestine, which, however, did not look inflamed The coil of worms was removed through a small incision, it contained about 30 ascarides of various sizes The near by loops were emptied by "milking" the worms in them towards the original incision, the latter was then closed A rubber drain was inserted, and the wound closed around it After the operation a course of 500,000 units of penicillin was given On May 31 the drain was shortened only sero sanguinolent discharge being seen There was one normal motion The drain was removed on June 2, and next day the general condition was satisfactory The abdomen was soft and not distended The patient took and retained his food, and the bowel action was satisfactory On the 5th he vomited five small ascarides Two days later his general condition deteriorated and he vomited worms on several occasions Next day there was further deterioration and he vomited twelve worms during the night On June 9 the patient died, extremely cachectic, choked with ascarides creeping in masses out of his nose and mouth

Discussion

Diseases due to roundworms play a considerable part among the abdominal troubles of the native population in the Middle East The clinical picture they produce may mislead the observer, unless he bears in mind their relative frequency in this part of the world as compared with Europe, and the possible variety of accompanying symptoms

In Case 1 it did not occur to us that roundworms might be the cause of the frequent abdominal spasms The boy's mother made no mention of their presence in the faeces, and examination led us only to the conclusion that operation was indicated because of clear signs of appendicitis with peritoneal involvement From previous experience we concluded that the masses palpable through the thin abdominal walls in Case 2 consisted of conglomerates of roundworms, the only disquieting sign was the raised temperature, which we had not found before in roundworm disease The success of the anthelmintic treatment confirmed our assumption and suggested that roundworms may cause inflammatory intra-abdominal changes, and the tenderness on palpation may be significant in that connexion The intense inflammatory changes in Case 3 reminded one of Crohn's disease However, the presence of a big mass of roundworms in the diseased intestinal loop led me to believe that they were the aetiological agent, not only grossly damaging the bowel wall but also causing the most severe inflammatory infiltration of the related mesentery Through an unfortunate accident we lost a swollen mesenteric gland which had been removed for histological examination during the operation Therefore and because the relatives refused permission to perform a post-mortem examination, no histological details are available

Summary

Roundworm infestation may become of surgical importance not only by causing mechanical obstruction of the small gut but by producing inflammatory changes varying in degree from trivial (Case 2) to the most serious conditions (Case 3) It is usually

difficult to distinguish this variety of inflammation from that of other origin Correct diagnosis will be facilitated if in regions with prevalent roundworm infestation one will bear that possibility in mind, and go into the history of the case accordingly, using also the laboratory methods for investigation

Surgical treatment will have to consider removal of as many worms as possible from the bowel, by "milking" them from adjoining loops towards an incision made over their biggest accumulation

I would not hesitate even to make more incisions in cases where very extensive infestation renders removal through one opening impracticable

At times the prognosis seems to depend to a considerable extent on the thoroughness with which the worms were removed during the operation As medical anthelmintic measures are not advisable for at least two weeks after incision and suture of the gut, the remaining worms have ample time to grow and flood the organism They may decide the fatal issue in cachectic individuals whose resistance through chronic roundworm infestation has already been lowered a long time before sudden developments compel them to seek medical advice

MESENTERIC VASCULAR OCCLUSION

BY

ERIC W. BINTCLIFFE, MBE, MS, FRCS

Senior Surgeon, Rinkwood Hospital Worcester

Mesenteric vascular occlusion is one of the less common abdominal emergencies It is extremely difficult to diagnose and the mortality rate is high, consequently scant attention has been paid to it in most surgical works In the past five years I have had two cases which recovered, and I feel that wider recognition and earlier treatment would do much to improve the gloomy prognosis

The first case was recorded by Tiedmann in 1843, but it was not until fifty years later that the first resection was performed (Elliott, 1895) In 1913 Trotter presented 359 cases collected from the literature, with seven personal cases Cokkims (1926) published a monograph embodying an exhaustive description of mesenteric vascular occlusion and the mesenteric circulation A series of cases was reported by MacLeod (1937) and by Atkins (1937), a case complicating labour was described by Grey Turner (1937), and two cases were recorded by Fallis (1940) A review of the literature was given by Brown (1940), and Moore (1941) followed with another, supported by eight cases In 1943 Luke described a case treated with heparin

Anatomy

For a proper appreciation of the possible consequences of mesenteric vascular occlusion an understanding of the anatomical arrangement of the blood supply of the intestine is necessary The whole of the small intestine and the large intestine as far as the middle of the transverse colon are supplied by the superior mesenteric artery This artery rises at an acute angle from the abdominal aorta behind the pancreas, crosses the third part of the duodenum, and passes forward into the root of the mesentery It gives off ten to fifteen intestinal branches and ends near the caecum by anastomosing with one of its own branches—the descending branch of the ileocolic artery One of its early branches—the inferior pancreaticoduodenal artery—anastomoses with the superior pancreaticoduodenal artery, which has its origin in the gastro-duodenal branch of the coeliac axis, and this forms a collateral channel if the superior mesenteric artery is occluded The branches of the superior mesenteric artery form numerous arterial arcades in the mesentery by anastomosing with each other These are more numerous in the lower ileac than in the upper jejunal region From the arcades the vasa recta which are true end arteries with no anastomoses, run to supply the gut-wall The large bowel as far as the middle of the transverse colon is supplied by the ileocolic, right colic, and middle colic branches of the superior mesenteric artery, the last-mentioned of which anastomoses with the left colic branch of the inferior mesenteric artery which is a separate branch of the abdominal aorta This is therefore another important anastomosis should the superior mesenteric circulation be interfered with Other anastomoses occur with the lumbar arteries in the retro-

peritoneal plexus. The venous drainage of the intestine follows closely the arrangement of the arterial supply, with the important difference that all the blood empties into the portal vein and not direct into the systemic circulation. This places the liver as a filter between the intestines and the systemic circulation, and any abnormality in the liver may have a profound effect upon the mesenteric venous circulation. Venous anastomoses between the portal and systemic veins occur in the haemorrhoidal and oesophageal plexuses and in the retro-peritoneal plexus, between the para umbilical veins and the abdominal wall, between the splenic and left renal veins, and between the left colic and capsular veins. Cokkinis (1926), in his injection experiments, found that the arterial collateral circulation, excluding the vasa recta, was considerable, and that the venous circulation was of even greater volume.

Pathology

The pathological manifestations of interference with the mesenteric circulation are various. When the circulatory obstruction develops slowly and gives time for the establishment of a collateral circulation, the changes in the intestine may be minimal consisting of oedema and congestion of the gut wall, patchy or diffuse, and intramural haemorrhage. Compensated vascular occlusion may be manifest clinically by a temporary ileus and complete recovery is possible if further extension of the damage does not occur.

More usually the vascular disturbance, whether caused by thrombosis or embolism, either arterial or venous results in gross pathological changes. The most common of these is haemorrhagic infarction of the wall of the intestine. The gut is at first congested swollen, and oedematous, then follow rupture of the capillaries and extravasation of blood throughout its wall. The gut becomes dull, plum coloured, stiff and inelastic, and gradually passes into a state of infective gangrene, becoming green or black. The changes are in fact the same as those in strangulated hernia. The extravasated blood also passes into the lumen of the intestine and into the peritoneal cavity. Some of that in the lumen may be passed on by a distal healthy portion of gut and give rise to bleeding per rectum, or it may be found in a diagnostic enema—an important point in differential diagnosis. The blood and oedema fluid in the peritoneal cavity give rise to a haemorrhagic peritoneal exudate, which is a very common finding. The affected portion of mesentery also undergoes gross changes, it becomes oedematous and friable, may be 1 in (2.5 cm) or more in thickness, and contains thrombosed vessels.

A very rare change is the development of anaemic gangrene in which a pale, bloodless infarct occurs, followed by putrefactive changes. The portion of intestine most commonly involved is the ileum, although in my own two cases it was the jejunum. No part of the intestine from the duodenum to the lower colon is exempt, and the extent of the affected area may be from a few inches to almost the whole of the intestine. An important point when considering treatment is that the limits of the infarcted area are not usually sharply defined but merge gradually into the normal portions.

Aetiology

The vascular occlusion may be primarily arterial or venous, the latter being the more common. As soon as the condition is developed however, both arteries and veins become thrombosed. This is owing to the tendency of the thrombosis to spread when the circulation has been slowed down, and is responsible for some of the failures after operative treatment. Arterial occlusion is usually embolic and affects the superior mesenteric artery more often than the inferior. It may result from mitral stenosis, mural endocarditis, atheroma, pulmonary vein thrombosis or pyaemia. Arterial thrombosis is usually associated with arterial degeneration, atheroma and arteriosclerosis being the common lesions.

Venous thrombosis may be due to a variety of causes. In many cases of mesenteric venous occlusion however no definite cause has been demonstrated. The number of such cases will probably diminish with a more diligent search for a causative factor. An important cause, and according to Cokkinis the most frequent, is peripheral sepsis in the portal area, arising

from appendicitis, pelvic infection, or diverticulitis. Any of these may lead to portal thrombosis or portal pyaemia. All the blood in the mesenteric venous circulation has to pass through the liver. There are many possible causes of obstruction to the portal vein by pressure from without, the most frequent and important being cirrhosis of the liver. Peripheral venous thrombosis may sometimes be a cause. Changes in the blood itself may predispose to thrombosis, and in this connection a blood disease such as polycythaemia rubra, leukaemia, splenic anaemia, or severe primary or secondary anaemia may be the initial lesion. Predisposing factors are debility, degenerative diseases such as alcoholism, inflammatory lesions, neoplasms, and occasionally mechanical factors such as trauma.

Symptomatology

Mesenteric vascular occlusion has the reputation of being almost undiagnosable. Its recognition is certainly difficult, but in a typical case there are features which should enable a diagnosis to be made if the disease is borne in mind.

No age is exempt, but the condition occurs most frequently between the ages of 20 and 50 (Cokkinis, 1926). Brown (1940) however, in an analysis of cases of venous occlusion found that the most common age incidence was between 50 and 60. The onset is associated with severe abdominal pain, colicky in character and centrally situated. This is often accompanied by considerable shock, and is followed by periodical recurrence of the colicky pain and vomiting. Borborygmi are often marked. The pain usually overshadows the vomiting, and this distinguishes the condition from most other types of intestinal obstruction. There is in some cases absolute constipation without passage of flatus, in others a motion may be passed containing altered blood. Melaena is an important diagnostic point and if blood is not passed spontaneously it may be found on the examining finger or be obtained from a high enema. Abdominal distension becomes apparent, and the abdomen is tender and rigid, often more so on the left side. The affected coils of gut may be felt as a palpable lump. Free fluid can usually be demonstrated. Leucocytosis is usually present and x-ray examination may show multiple fluid levels. As time goes on the patient becomes severely ill with marked shock, subnormal temperature, rapid pulse, and low blood pressure. In fact he resembles a late case of intestinal obstruction with peritonitis. In cases of massive occlusion the element of obstruction may be overshadowed by the signs of internal haemorrhage due to the large amount of blood which may be lost into the infarcted intestine. Some of this haemorrhage may be external and become evident as haematemesis or melaena.

Diagnosis, Prognosis, and Treatment

In Trotter's large series the correct diagnosis was made in less than 5%. In the cases described by Cokkinis the diagnosis was established in approximately 15%, but many others in this group presented symptoms which should have made a diagnosis possible.

Important points to note in attempting to establish a diagnosis are (1) a history or signs of a possible causative lesion—for example, endocarditis or cirrhosis, (2) the presence of blood in the bowel, either passed by the patient or found on examination by the enema test, (3) the presence or previous history of vascular occlusion elsewhere, (4) the presence of a blood dyscrasia, (5) severe pain often greater on the left side, associated with signs of intestinal obstruction, free fluid, and sometimes a palpable lump. The differential diagnosis from other causes of intestinal obstruction, perforated peptic ulcers, and acute pancreatitis has to be made.

Of untreated patients more than 95% die, only those with a mild attack in whom an adequate collateral circulation is established will survive. With treatment the general mortality in cases of venous occlusion is approximately 68% (Brown 1940), with a higher figure obtaining for arterial embolism. The mortality depends in part upon the amount of gut involved and the prognosis improves if the length infarcted is less than 3 ft (0.9 m), although recovery with normal function has followed the removal of half of the small intestine.

Exploratory laparotomy should be undertaken early. The time factor is as important as in cases of perforated ulcer, and

more important than in most cases of obstruction. The patient should be rendered as fit as possible by intravenous therapy before operation. As soon as the abdomen is opened free blood stained fluid will be encountered in considerable quantity. The affected portion of intestine is usually quite obvious, and if it does not actually present in the wound it can easily be found. Wide resection of the bowel should be performed, leaving a good margin of healthy tissue on each side of the infarcted segment, together with similar treatment of the affected portion of the mesentery. The presence of a second infarct in some other segment must not be overlooked. Continuity can be re-established by means of end-to-end or lateral anastomosis. If the large intestine is involved resection, with external drainage, should be performed, and continuity established at a later date. Exteriorization is not good treatment for the small gut, in one such case described by Atkins the complications were many and troublesome, although the patient finally recovered. Even the most desperate cases may be given a slender chance by the establishment of an enterostomy.

Case I

A printer aged 50 experienced a sudden attack of abdominal pain working all night. The pain was colicky in nature and became so during next day he vomited three times, but his bowels had not opened. Two high wash outs were given by his doctor without result, there being absolute constipation from 9 a.m. No blood was obtained with the wash out. On admission to hospital he was doubled up with pain, the temperature was 97.6°F (36.4°C), pulse 84. His general condition was healthy and there was no pulmonary or cardiac disease, sepsis, or thrombosis. The abdomen was moderately distended and very tender all over. An ill defined tumour measuring several inches across was present in the centre of the abdomen. It was dull to percussion, there was also dullness in both flanks. Borborygmi were heard. The severe colicky pain was relieved by morphine. A diagnosis of intestinal obstruction was made and a laparotomy performed under spinal anaesthesia. On opening the abdomen blood-stained fluid escaped and a large loop of engorged gangrenous small intestine was seen. Further examination showed that 2½ ft (0.76 m) of the lower part of the jejunum was involved with its mesentery, which was much thickened and oedematous. There was a gradual transition to healthy intestine on both sides of the infarcted portion. The affected portion, including its mesentery, was resected, blind ends were made, and continuity was re-established by side to side anastomosis. The abdomen was closed without drainage, and convalescence after operation was uneventful. The patient was discharged from hospital seventeen days after operation, and at the time of writing was quite well and leading a normal life.

Case II

A regimental sergeant major aged 38 was admitted to hospital complaining of abdominal pain. He first experienced pain across the lower abdomen and in the left flank two years previously, it was sudden in onset and shooting in character. The abdomen became very distended and the patient vomited. His bowels had not opened, and the pain was so severe that he fainted in bed. The attack subsided spontaneously. Later he had another severe attack and several milder ones of the same nature, and he was admitted to hospital. As the pain was mainly in the left flank he was subjected to a complete renal investigation, with negative results. The day after his discharge from hospital he had his most severe attack, and then came under my care.

On examination his general condition was fairly good. The tongue was coated and dry and the heart normal, blood pressure 150/90. The lungs were healthy, the haemoglobin was 70%, and the Wassermann reaction negative. The abdomen was moderately distended, rigid, and tender, the maximum tenderness being to the left of the umbilicus, where a vague mass could be felt but not accurately defined. There was dullness in the flanks, and borborygmi were marked. The rectum was empty and ballooned, and there was no blood on the examining finger. An enema produced no blood, mucus, or flatus. A diagnosis of intestinal obstruction was made.

Laparotomy was performed under general anaesthesia. On opening the abdomen a considerable quantity of blood stained fluid escaped. The vague tumour which had been felt on the left side of the abdomen was found to be two coils of deep plum coloured jejunum matted together and covered with flakes of fibrin. The mesentery was more than 1 in (2.5 cm) in thickness, and its vessels were seen to be thrombosed. Some 3 ft (0.9 m) of the upper jejunum was affected and this portion was resected, blind ends were made, and a side-to-side anastomosis was performed, keeping well clear of the infarcted region. After division of the mesentery, it could be picked out of the vessels. The anastomosis was found to be 1 ft 6 in (45 cm) distal to the duodeno-jejunal flexure. A

pint (568 ml) of plasma was given during the operation, followed by intravenous saline and glucose. Convalescence was complicated by a post operative bronchitis, but the patient passed flatus on the third day and the bowels acted spontaneously on the fourth. The chest soon cleared, and thereafter convalescence was smooth. It was a considerable time, however, before this man regained his appetite and began to put on weight. After a period at a convalescent home he was regraded category C (temporary) and returned to his Army duties free from symptoms. Histological section of the tissue removed showed a primary venous thrombosis, the cause of which could not be determined.

Discussion

Both of the above cases had a primary venous thrombosis of limited extent. Consequently they responded well to early operation and resection of the affected segment of the bowel. Fortunately, no further spread of the thrombosis occurred after operation, as sometimes happens. An important point in preventing this is to make the resection through healthy bowel and to remove all the affected portion of mesentery. In neither case was the diagnosis made before operation, although it was immediately obvious on opening the abdomen. Both cases presented the appearance of an early intestinal obstruction but in neither was there a key sign such as haemorrhage from the bowel, evidence of cardiac disease, or venous thrombosis elsewhere, to suggest mesenteric occlusion. In the second case the only possible predisposing cause that could be found was a moderate degree of secondary anaemia. The pain in the left flank was a pronounced feature and had led to a complete renal investigation at another hospital before the pre-operative thrombosis occurred. Loin pain was also found by Fallis. It is possible that it occurs fairly constantly on the left side when the upper part of the jejunum is involved. It was noted during convalescence that a considerable time was required for the re-establishment of the appetite and a gain in weight, and this was thought to be due to the removal of a large portion of the active absorption area of the jejunum. The presence of a palpable lump is stated by Cokkinis and others to be unusual, and most of the statistics substantiate this. Its occurrence in both my cases was fortunate, but it is in no way diagnostic since there are so many possible causes of intestinal obstruction associated with a palpable mass. However, if it is associated with evidence of bleeding this sign is of greater value. The occurrence of previous similar but less severe attacks of pain in Case II was thought to be due to a small venous thrombosis in the mesentery resulting in a temporary ileus, with recovery on establishment of an adequate collateral circulation.

Treatment in each case was early operation with resection in an established case this gives the patient his only chance of survival. Both these patients were in quite good condition, and the length of the intestine involved was not great. This contributed in no small measure to the favourable results. If the large intestine is involved resection with drainage of both ends is the treatment of choice, but if this method is applied to the small bowel it is liable to be followed by troublesome complications (Atkins, 1937). What can be accomplished by bold surgery is shown by a consideration of Grey Turner's (1937) remarkable case complicating pregnancy in which 10 ft (3 m) of small intestine was resected and a Caesarean section performed at the same time. The patient survived, led a normal life, and had another pregnancy. The possibility that an anticoagulant such as heparin may be of use in the treatment of this condition has been considered, and Luke (1943) published a case treated by this means. The case was an early one of venous thrombosis involving the jejunum, and was proved by laparotomy. The wound was then closed, and 21,000 units of heparin were given in 21 litres of saline during the succeeding 10 days. The coagulation time was estimated six-hourly and was found rather difficult to control owing to variations in the rate of drip. A complete recovery ensued. Any case in which this treatment is adopted must necessarily be an early one, before serious infarction has occurred, otherwise there is a danger of profuse bleeding into the infarcted bowel or peritoneal cavity. Haematoma formation may occur in the laparotomy wound. It is doubtful whether cases can be obtained early enough for this treatment. However, it does seem that there is a possible field of usefulness for heparin when combined with operation, with a view to preventing any extension of the thrombosis. Earlier diagnosis and prompt

treatment are the keynotes to success in this very serious abdominal emergency

Summary

The anatomy, pathology, and aetiology of mesenteric vascular occlusion are described, and some of the literature is reviewed

Symptomatology and diagnosis are considered and a plea is made for the earlier recognition of the disease. The importance of signs of cardiac, vascular, or blood disease, or of any evidence of haemorrhage from the bowel, is stressed

Two personal cases, with recovery, are presented

Treatment is discussed and the possibilities of the use of heparin are considered

I wish to express my thanks to Surg Lieut C J Bintliffe and Dr J G Winternitz for their help in the treatment of the patients to Dr S J Scurlock, medical superintendent of Ronswood Hospital, for his kind assistance in the preparation of the paper and to the Director General of Medical Services, Ministry of Pensions, for permission to publish

MYOPATHY WITH SPINA BIFIDA

BY

RONALD G PALEY, MB, MRCS
Capt R A M C

The following is an unusual and interesting case of myopathy associated with spina bifida

Case History

The patient was a soldier, aged 30, formerly a country bus-driver. His paternal grandfather lived to a healthy old age. His father died of 2 meningitis at 28, his mother at 45 from "tumour" of the uterus. He had no brothers, but there were two half sisters by the same mother, both healthy. The patient had no knowledge of any familial disease.

In childhood he had no serious illness, but at school he noticed weakness of his legs. He became a gardener, but found the work too hard. In February, 1941, he had pneumonia and was in bed five weeks. During a protracted convalescence there was increased weakness, with wasting of the muscles of the chest and abdomen. For the last two and a half years the condition had steadily progressed. At no time had his muscles been bulky.

His height was 65½ in (1 66 m). His face was thin and expressionless, and wasting of the muscles of the shoulder girdle and winging of the scapulae were present. There was no wasting of the forearm or small muscles of the hand. Active and passive movements were free and power good. Marked wasting of the erector spinae was obvious (see figs). The abdomen was scaphoid, with wasting of all muscles except the erector abdominis. The muscles of the pelvic girdle all showed pronounced wasting, those of the lower leg and foot were not wasted, but there was a mild pes planus. Movements were full and power only slightly reduced. No muscular fibrillation was observed.

The spine showed scoliosis and a depression in the region of dorsal vertebrae 11 and 12, with a palpable gap. In this depression there was a non-hairy, non-pigmented mole. Radiographs confirmed non union of the posterior arches of these two vertebrae.

The blood WR was negative, the CSF normal and WR negative, and the urine normal. No electrical reactions were taken. Although the cardiovascular system was normal, there was moderate tachycardia. The blood pressure was 120/80. Chest expansion was poor—only half an inch (1 25 cm) in the nipple line. The breathing was almost entirely abdomino diaphragmatic. Radiographs showed some evidence of chronic bronchitis at the bases. Diaphragmatic movements normal. All the cranial nerves were normal and all reflexes were present, although the abdominal reflexes were very weak. There was no sensory disturbance. No vasomotor or trophic changes were present.

Discussion

Exhaustive search through the literature of the last 25 years revealed only one other case of this association of conditions. Urechia and Dragomir (1942) described a case of myopathy

with a spina bifida occulta of the first sacral vertebra. With respect to the regions of muscular atrophy and the absence of sensory disturbance their case resembled the one now reported. In certain features it was different: there was a heredo-familial trait, one sister and a nephew suffering from myopathy. A hypertrophic stage had occurred. The progress of the disease was more rapid, and the patient was bed ridden at the age of 25. Their case was remarkable for a large pigmented hairy mole covering the right half of the abdomen.

The location of the bifida in the thoracic spine is not common. Wheeler (1920) found no evidence of spina bifida in 3 000

FIG 1

FIG 2

thoracic vertebrae seen at the National Museum, Washington. Hadley (1941), examining a series of 1,500 consecutive spinal cases, found 3 instances of spina bifida in the thoracic region.

It is interesting to note that in the literature over the same period there are two recorded cases of spina bifida associated with a different form of muscular atrophy. In 1925 Guillain, Mathieu, and Garcin described a case of Charcot-Marie muscular atrophy with spina bifida of the first two sacral vertebrae. Heuyer Hurez and Feld (1942) reported a similar case.

It is difficult, if not impossible to decide whether the occurrence in the same patient of two uncommon pathological conditions (myopathy and spina bifida) is due to chance concurrence or to some common aetiological factor—e.g. genetic make-up. Urechia and Dragomir (1942) quote numerous authors who have described various osseous deformities in cases of myopathy. Nevertheless during the last 25 years this particular association has been noted only once before in the literature on myopathies. This suggests that chance concurrence is the more likely explanation.

Summary

A case of myopathy with spina bifida is reported. The literature has been examined. One other reported case has been discussed and compared. The comparative rarity of spina bifida in the thoracic region has been noted. The association of the two conditions is thought to be a coincidence.

I wish to thank the Director General Army Medical Services, and Lieut Col M I Silverton R A M C for permission to publish this case.

The Hospital Survey and Construction Act of the United States which authorizes the nation-wide building of hospitals, requires that standards for the construction of all those built with Federal assistance under this scheme shall be defined by the U.S. Public Health Service. These standards which are minimal, were recently drafted by the Federal Hospital Council has now accepted them. They fall into five classes: site, architectural, structural, mechanical (e.g. ventilation, plumbing, electrical fittings) and drawing specifications.

Medical Memoranda

An Unusual Case of Intestinal Myiasis

A primipara aged 40, during a routine visit to the antenatal clinic of Queen Mary's Hospital, London, E., produced a bottle containing three small white grubs about 5 mm in length which on cursory examination were thought to be the larvae of some fly. I questioned her as to the history of these grubs and she told me the following story.

For the last two weeks she had been suffering from frequent attacks of diarrhoea and constipation accompanied by some general abdominal pain of a colicky nature. After noticing a few flecks of bright blood in her stools she had examined them more carefully and on about four occasions just before seeing me she had passed two or three of these grubs, all of which showed signs of life. This alarmed her considerably, and she saved some of the specimens for further examination. I questioned her very closely as to the possibility of outside contamination, and she stated that this was absolutely impossible as all the specimens were quite fresh. As she is a patient of very clean habits and of average intelligence I consider her story to be true in every respect.

The treatment consisted in giving one fluid ounce of liquid paraffin at night for seven days, and this appeared to clear up the condition, for she has had no further symptoms or signs to date.

The grubs were sent to Dr Fritz Van Emden at the Imperial Institute of Entomology, British Museum. They were identified as the larvae of *Pinus tectus* Boield. The adult is a yellowish-brown coleopterous insect about 3 mm in length. Dried cereal foods are its favourite habitat, and upon these the eggs are laid. It is difficult to understand how the larvae can withstand passage through the stomach, but it is possible that the eggs, which have a resistant chitinous coating, may do so with subsequent hatching in the more alkaline portion of the bowel. Survival and growth here would be possible. The larva is covered with a growth of fairly thick pubescence arising from each segment of the body. The six legs each contain a single sharp claw and the biting jaws are quite formidable. By reason of this armament larvae can remain in the intestine for a considerable period, clinging to the villi and thus resisting peristalsis. The photomicrograph demonstrates some of the points mentioned.

Photomicrograph of larva of *Pinus tectus* Boield, from the above case. Magnified 10 diameters, dark background illumination.

From the above short description of this unusual case it would seem that the infestation of the intestine by insectivorous larvae, which though recognized in the textbooks on parasitology is not, I believe, given much thought in this country, should be considered when one is diagnosing a case of diarrhoea accompanied by colicky pain and the passage of blood per rectum. One has only to consider the enormous population of flies and other insects which inhabit this country in the summer and autumn, gaining access to all manner of foodstuffs no matter what precautions may be taken, to see how easily infection could arise. To give one example we all know how swarms of flies besiege a tree of ripening plums, feasting themselves upon the fruit, and as most insects lay their eggs on their foodstuffs in order that their larvae may gain sustenance, it would appear that these infected fruits would become an excellent vehicle for the infestation of man—especially when one considers how many children eat fruit without inspecting its contents. Thus it would seem that intestinal infestation with insectivorous larvae, known as myiasis, may be by no means as uncommon as we are led to believe.

My thanks are due to Dr Fritz Van Emden for his part in identification of the larvae to Dr J S Sharpe for preparation of this specimen for examination by the microscope and for the photograph and to Mr Andrew McAllister FRCS, FRCOG for his permission to publish the case.

D S SHARPE, MRCS, LRCP

Severe Adult Diphtheria with Polyneuritis

During September, 1945, to February, 1946, inclusive, 100 cases of acute adult diphtheria were admitted to the 94th British Military Hospital, Hamburg. In the December and January there had been an epidemic type of severe faucial diphtheria the clinical picture being gross toxæmia with membrane covering tonsils, uvula, and palate, bull neck adenitis, and severe polyneuritic complications. Sporadic cases of this type had been observed in Holland and Belgium during the previous winter. Another important feature was the late onset of polyneuritis in cutaneous diphtheria. On admission the average duration of disease was three days, 60% were direct admissions.

TREATMENT

The minimum period in bed was five weeks, and four clearance swabs were taken from the twenty-eighth day of disease. Uncomplicated cases were discharged to the convalescent depot at the end of seven weeks and complicated cases were evacuated to the U.K. when fit to travel.

Antitoxin Dosage—Nasal and aural 24 000 units, intramuscularly. Mild faucial unilateral membrane 24,000–48 000 units intramuscularly. Moderate faucial, bilateral tonsillar membrane with little toxæmia 48 000–80 000 units intramuscularly. Severe faucial all cases received 80 000 units intravenously, repeated if necessary, the standard being the shrinkage of membrane and decrease of the bull-neck adenitis.

Penicillin Dosage—All severe cases of faucial diphtheria were also given 200,000 units of penicillin daily for three days by continuous intramuscular drip. Cutaneous diphtheria cases had four hourly penicillin spray, 500 units per ml applied to the ulcers, as well as intramuscular diphtheria antitoxin.

The type of Klebs-Loeffler bacillus showed no relation to the severity of the disease. Of the severe faucial cases six were of the gravis and five of the mitis type, although in the whole series the gravis type predominated. Of the mild faucial cases one had polyneuritis after eight weeks. Four of the moderate faucial cases had polyneuritis, beginning as early as the end of the fifth week and as late as the twelfth week. Ten of the severe faucial cases had polyneuritis beginning from the end of the fifth week to the tenth week. The typical picture was a palatal paralysis at the end of five weeks followed by a pharyngeal paralysis at the end of six weeks and generalized polyneuritis at the end of seven or eight weeks. Five patients had to be fed by nasal catheter for 15 days. Two had respiratory paralysis one having to stay five days in the Both iron lung, being fed by nasal catheter. In all cases complicated by polyneuritis the period in hospital before evacuation to the U.K. was from 12 to 18 weeks. In the 100 cases recorded there was one death, due to early cardiac failure on the twelfth day.

Intramuscular penicillin did not seem to have any dramatic effect in preventing the spread of faucial membrane, reducing toxæmia, or preventing polyneuritic complications. Similar results have been reported by Dodds (1946) and Christie and Preston (1946), but as *C. diphtheriae* is penicillin sensitive (MRC War Memo, 1944, No 12), penicillin should be given in all cases of severe diphtheria. Three of the 15 severe faucial cases had positive KLB in the throat after 28 days in spite of 600,000 units of intramuscular penicillin.

Three of the seven cases of cutaneous diphtheria developed polyneuritis, and in each the original ulcer began on the penis. These cases were seen late and had large ulcers of the penis and suprapubic area. From previous experience penicillin spray four hourly healed the ulcers quicker than the local application of diphtheria antitoxin. Owing to the late onset of polyneuritis the standard adopted was that, when the ulcers had healed, that date was put on the patient's chart as the first day of disease. Local paralysis around the ulcer areas was observed and also visual paralysis along with the polyneuritis.

SUMMARY AND CONCLUSIONS

Faucial diphtheria can be a very dangerous and prolonged disease of adult life.

Cutaneous diphtheria cannot be missed in the early stages and severe as those of faucial diphtheria. Dosage mentioned has no dramatic effect or in reducing the convalescent carrier rate.

Early intravenous diphtheria antitoxin is still the best line of treatment although it does not prevent polyneuritic complications.

I should like to thank Lieut Col Porter, R.A.M.C. Major Hinson R.A.M.C. and Dr A.H.G. Burton late M.O.H. for Ilford for their great help and advice.

GRAY'S ANATOMY

Gray's Anatomy Descriptive and Applied Edited by T B Johnston, M D, and J Whillis, M D, M S Twenty ninth edition (Pp 1597, 1359 illustrations, of which 642 are coloured and 47 are x ray plates 70s) London Longmans Green and Co 1946

The appearance of the twenty-ninth edition of *Gray's Anatomy* will be welcomed by students practitioners, and teachers of anatomy Well-illustrated and with a descriptive text in which all essential facts are plainly stated without verbosity, it has from its first appearance in 1858 been one of the most deservedly appreciated textbooks which make up a medical student library The present edition, revised and brought up to date by the inclusion of much recent work, has been edited and in parts rewritten by Prof T B Johnston and J Whillis of Guy's Hospital, while the section on the digestive system has been undertaken by Prof Francis Davis of the University of Sheffield

The need for a good textbook of systemic anatomy in addition to a book on regional anatomy or a dissection manual is well supplied by the present volume, which, though not aiming at the completeness of some of the larger Continental works published in several volumes, each comprising a particular system, nevertheless forms a reliable guide to much new matter which is of practical importance and to which adequate references are supplied as footnotes to the text The notes also on applied and surface anatomy are a feature of special value as giving indications for the examination of patients for fractures or dislocations, and also for medical or surgical examination of internal organs In this last connexion we should like to mention the excellence of the numerous plates reproducing radiographs of the epiphyses, movements at articulations, and the relative positions and shape of internal organs

The section on embryology comprises much new matter on the early stages of development, and many new illustrations, such as those showing the method of homotypical and heterotypical division of chromosomes, and photographs of various stages in the embedding of the human ovum in the uterine mucosa, representing recent work of American authors such as Hertig and Rock and also early stages of development of the heart and blood vessels by Heuser, Streeter, and C L Davis The role of chromosomes in sex determination and in human genetics has been ably dealt with in a short account of the theory concerning the mode of distribution of genes in the various blood groups, and the effects of their transmission from both father and mother through the oosperm to the embryo and foetus The description of the central nervous system has been amplified by the inclusion of current conceptions of the functions of the various nuclei of the brain and spinal cord, and more particularly of the basal nuclei and hypothalamus, including a description of the routes by which co ordination of these functions by tracts of nerve fibres may be effected these tracts being clearly indicated in the figures by the use of distinctive colours

Any points in the book that call for critical comment are rather in the way of omissions than commissions—e.g., in the description of the breast one would have liked to see an account with illustrations of the successive stages in its development *in utero*, and also of the microscopic structure of the lactating gland for comparison with the resting condition of the organ, moreover from the morphological standpoint an account of the evolution of the glands as indicated by a study of their condition in lower mammals and the significance of the development of nipples in the male would have added greatly to the general interest of the purely anatomical description The addition of a glossary also would in our opinion be a very welcome feature in any subsequent editions or reprints of the present volume *Gray's Anatomy* considered as a whole is an authoritative standard work suitable for the use of both junior and senior medical students and a most valuable book of reference for practitioners and for all teachers of human anatomy

INSTRUCTION IN GYNAECOLOGY

Textbook of Gynecology By Arthur Hale Curtis, M D Fifth edition (Pp 756, 455 illustrations, chiefly by Tom Jones including 36 in colour 40s) London and Philadelphia W B Saunders Company 1946

Prof Curtis's popular textbook has been extensively revised in its fifth edition, which is as beautifully produced as its predecessors The illustrations throughout are superb, the coloured plates being particularly so The text is clear and for the most part dogmatic—a feature that will commend the book to many readers but lessen its value to others Most teachers will agree that undergraduates not only desire but require such teaching General principles clearly and unequivocally expressed provide a foundation on which a more detailed knowledge can be built but none the less the undergraduate should be encouraged to develop a critical mind He should be taught the difference between facts and theories, and if these are not separated in the teaching of his mentors he cannot be blamed if he rejects as doubtful or inaccurate and unorthodox instruction he may be given

Senior students and young specialists are likely to be even more critical of this book and for the same reason It is not enough for an author to deny the value of endometrial biopsy as an aid to diagnosing genital tuberculosis, when increasing numbers of publications from many different workers in various parts of the world are drawing attention to its importance nor is it convincing to be told that urethroplasty is an adequate method of treating all cases of stress incontinence of urine when the results in good hands are so notoriously uncertain that many more extensive operations of the sling type have been designed for intractable cases Similarly the bald statement that abortion is a common cause of sterility is one which has been accepted for a long time but in view of the national and international importance of the whole subject of fertility the accuracy of such statements is now being widely questioned If it is true it should be confirmed by facts but none is offered It is somewhat strange in this connexion that the author states that the average intelligent physician should learn to care for his sterile and subfertile patients with results closely rivaling those of his highly specialized colleagues Surely the whole subject of fertility is now so complex that this is barely possible nor would the guidance given in this book to the practitioner be sufficient to make it so The statement that, if a subtotal hysterectomy is performed on a patient in whom carcinoma of the corpus is suspected, the operation should be performed so as to avoid "spill" and the specimen opened in the theatre is another illustration of strange teaching

In spite of the criticisms given, this is an excellent book and already widely popular, as such it should be careful to raise the standard of practice and not imply a willingness to compromise to the possible or probable detriment of the patient's welfare If the surgeon is not competent to perform a total hysterectomy he should not be operating on a case of suspected carcinoma of corpus, and if he is competent he should be able to diagnose the condition before resorting to an inadequate hysterectomy A textbook such as this should give guidance in such matters

PSYCHIATRY FOR NURSES

Psychiatry Theory and Practice for Nurses By H C Beccle, M B, M R C P, D P M (10s 6d) London Faber and Faber

This book purports to be a textbook for mental nurses training for their final examinations In the preface the author bemoans the lack of understanding of human behaviour and the curious attitudes which men and women take towards life which lead to so much unhappiness from the nagging wife or irritable father to major war In the book however we find a comprehensive summary of the anatomy and physiology of the nervous system and practically all nervous and mental illness compressed into 240 pages If a doctor knew all the "facts" contained in this volume he would have the basic knowledge needed for specialism but whether he would be a competent neurologist or psychiatrist is another matter It is still more doubtful if the acquisition of this knowledge by a nurse would make her a competent person to alleviate the miseries of those who are "sick in spirit"

If this book, whose author displays so much erudition and indeed clarity and accuracy of exposition is needed for the training of the mental nurse, it forces us to ask ourselves whether we are not entirely on the wrong lines in the training of nurses. So far as mental illness is concerned the real understanding of the general nurse is conspicuous by its absence through no fault of the nurse and only gradually is the psychiatrist himself beginning to know how to deal with true sympathy with his much afflicted patient. Is his chief assistant best trained by cramming her head with bare facts? Time alone will tell. Meanwhile, the aspirant to nursing qualification will find in this book all the factual material she requires. What she will make of this, and how she will use it, probably depends more on herself than on her teachers.

FIRST LINES IN BACTERIOLOGY

A Textbook of Bacteriology and Immunology By Joseph M. Dougherty, M.A. Ph.D., and Anthony J. Lambert, M.S. (Pp 360, 102 illustrations 22s 6d) London: Henry Kimpton 1946

Bacteria in Relation to Nursing By C. E. Dukes, M.D., M.Sc. D.P.H. (Pp 186, 20 illustrations, including 12 in colour 12s 6d) London: H. K. Lewis and Co. 1946

Aids to Bacteriology By H. W. Scott-Wilson, B.Sc., B.M.B.Ch. Seventh edition. The Students' Aid Series (Pp 300 6s) London: Baillière, Tindall and Cox 1946

A Textbook of Bacteriology and Immunology by J. M. Dougherty and A. J. Lambert, of Villanova, Pa., U.S.A., is based on experience in teaching 'premedical' and 'pre-dental' students and those 'preparing to teach the biological sciences'. As an introduction to the subject for such students it is excellent, for the medical student in his clinical years it is inadequate. It is a very readable book, in which the authors' aim to make the subject both interesting and easily intelligible has been well achieved. The introductory chapter on the development of the science is particularly good, as are those on general principles and methods. The descriptions of individual bacteria and of their relation to disease and laboratory diagnosis are simple and incomplete. To give examples, there is no mention of the coagulase test, the serological classification of haemolytic streptococci, types of diphtheria bacilli or how to interpret the results of an agglutination test in the diagnosis of enteric fever. This book is therefore only introductory, and its title might well be altered to convey this.

Bacteria in Relation to Nursing by C. E. Dukes, is intended for those training to be sister tutors, but may be found useful both practically and in preparing for examinations by nurses generally. It is written in a clear and pleasant, almost conversational, style and is attractively produced and well illustrated by drawings. There are only two photographic illustrations both showing nurses in uniform working in a laboratory. The main subjects are methods, the characters of the principal pathogenic bacteria, immunity, the collection and examination of various kinds of specimen, and sterilization and disinfection. A final chapter outlines a suggested course of practical instruction. The necessary simplification has been achieved without sacrifice of truth, but there are a few minor inaccuracies. It is said that agar is obtained from algae and that diphtheria bacilli will not grow in broth. It is hard on Dubos to describe gramicidin as a purely Russian discovery, and the mention of convalescent serum for the treatment as well as the prevention of measles may mislead. In the next edition we should like to see at least a paragraph explaining what viruses are (they are only incidentally mentioned in two places) and perhaps something similar might be done for protozoa.

The seventh edition of *Aids to Bacteriology* by H. Scott-Wilson, is said to have been completely revised but almost archaic features of much earlier editions survive in it and many modern advances are unmentioned. The characters of growth in gelatin and on potato are regularly described, one would prefer in connexion, for instance, with typhoid and dysentery bacilli to be told of some of the highly selective media which now facilitate their isolation. The greater part of the book 'dates' to twenty or more years ago and if it is to be of use to medical students it should be rewritten preferably by a teacher familiar with their needs.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Phases in the Drinking History of Alcoholics By F. M. Jellinek, Sc.D. (Pp 88 \$1.00) Connecticut: Hillhouse Press 1946

A study of the behaviour of chronic alcoholics based on replies to a questionnaire, from the laboratory of applied physiology, Yale University.

Principles of the Contact Lens By H. Treissman, F.R.C.S. D.O.M.S., and E. A. Plaipe (Pp 88 10s 6d) London: Henry Kimpton 1946

Intended for ophthalmologists. General description of contact lenses, their optical merits, and tests of suitability for patient.

Intelligence and Fertility By Sir Cyril Burt, M.A. D.Sc. (Pp 43 2s) London: Hamish Hamilton 1946

Survey prepared at request of Royal Commission on Population. Investigates problem of whether differing birth rates in different sections of the population will alter the inherited mental qualities of the nation.

Ambulatory Proctology By A. J. Cantor, M.D. (Pp 524 42s) London: Hamish Hamilton 1946

An American study of ambulatory surgical and medical treatment of diseases of anus, rectum, and colon.

Dentistry: An Agency of Health Service By M. W. Carr, D.D.S., and others (Pp 219 \$1.50 8s 6d) New York: The Commonwealth Fund 1946

A survey of the history, present problems, and future trends of dentistry in the United States.

The Hospitals Year-Book, 1945-6 Edited by J. P. Wetenhall, B.A. (Pp 279 No price) London: The British Hospitals Association 1946

The fourteenth issue of this directory of the units composing the nation's hospital services including a review of the last decade and current events.

A Textbook of Clinical Neurology By J. M. Nielsen, B.S. M.D. F.A.C.P. Second edition (Pp 699 \$7.50) New York and London: Paul B. Hoeber (Harper and Bros.) 1946

Designed for students and practitioners. Covers the whole field of clinical neurology. New subjects treated include toxoplasmosis, neuromuscular exhaustion and penicillin therapy. Many illustrations.

Researches on Pre-Natal Life Volume I By Sir Joseph Barcroft (Pp 292 37s 6d) Oxford: Blackwell 1946

Brings together the author's researches on the subject. Topics discussed include function of the placenta, influence of diet on growth of foetus, the foetal circulation, utilization of oxygen prenatally and neonatal circulation.

Nutrition in Public Health By Lucy H. Gillett, M.A. (Pp 304 14s) Philadelphia and London: W. B. Saunders 1946

Intended to instruct parents and teachers in the basic principles of nutrition, the planning of meals, special diets and racial food customs.

Précis d'Anatomie Neurologique By Jacques Huguier (Pp 312 200 francs) Paris: Librairie Maloine 1946

The anatomy of the nervous system in summary and diagrammatic form. Profusely illustrated.

L'Ophthalmologie du Practicien By A. Cantonnet. Ninth edition (Pp 172 100 francs) Paris: Librairie Maloine 1946

A concise outline of ophthalmology for the practitioner.

RKG Rheocardiography By W. Holzer, K. Polzer and A. Marko. English translation by E. M. Kreidl (Pp 43 7 Swiss francs) Vienna: Wilhelm Maudrich 1946

An electrocardiographic investigation of the cardiovascular system.

The Chemistry of Anaesthesia By J. Adriani, M.D. (Pp 530 35s) Oxford: Blackwell 1946

The book is in three parts: (1) inorganic phases of chemistry related to anaesthesia, (2) organic chemistry, and in particular the chemistry of depressant drugs, (3) biochemical aspects of anaesthesia. The fruit of the author's postgraduate teaching at New York University College of Medicine.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 11 1947

THE PRESIDENTS AND MR BEVAN

The three Presidents of the Royal College of Physicians, Royal College of Surgeons, and Royal College of Obstetricians and Gynaecologists on Jan 2 wrote a letter to the Minister of Health on what the *Times* has described as the growing gulf over the National Health Service between the doctors and Mr Bevan. On Monday of this week the Minister of Health replied to the Presidents' letter. Both communications are published in the middle pages of this week's *Journal*. These two documents are of the highest importance and deserve the closest study by the medical profession. The three Presidents express concern over "the opposition of a substantial part of the medical profession to any renewal of discussions" on the National Health Service. They wish to prevent an impasse arising. They believe that the form of the Service will depend to a large extent upon the Regulations and that several objections of the profession may be met in the framing of these Regulations. They therefore ask the Minister to clarify some points. The first is the fear of many doctors that in entering into discussions on the Regulations they would imply approval and acceptance of the main provisions of the Act. So far as the general practitioner part of the Service is concerned the Presidents bring to the notice of the Minister three points for reconsideration: the basic salary, the tribunal, and "the liberty of movement of general practitioners. As to specialist practice in the new Service, they state: "In the background, just as in the case of general practitioners, there is the general issue of the freedom of the profession and the availability to the people of independent medical advice." They stress the profession's desire for the continuation of independent practice.

The Minister in his reply assures the Presidents that there is no ground for the fear that in discussing Regulations medical men "would compromise their position by implying their approval and acceptance of the main provisions of the Act." He adds: "Every doctor will have to decide for himself when the proper time comes whether or not he should take part in the new Service, and the profession as a whole will be free to determine their views on the Service when they know what it is to be. The resumption of discussions now would not prejudice these eventual decisions." The Minister goes on to ask for the profession's "help and advice in this task"—that is, in framing Regulations. "I shall endeavour," he observes, "to meet any views of the profession which do not conflict with the principles of the Act." He states his readiness to discuss the question of the basic salary, observes that in the new Service the full civic rights of doctors will be preserved, and states "there is no power to direct a doctor to go anywhere or do anything." On the question of professional freedom the

Minister writes: "It is a basic principle of the new Service that there should be no interference with the clinical freedom of any doctor—specialist or general practitioner. It is also a principle of the Service that "independent specialist practice should be free to continue."

We conclude with this comment in a leading article in the *Times* of Jan 6: "Yet a crisis of confidence has been precipitated, and it cannot be denied that Mr Bevan himself has helped to precipitate it. Can this crisis of confidence be resolved, and does the Minister's letter contribute to this desirable end? At their Division meetings before Jan 28 members of the B.M.A.—with the final figures of the plebiscite in front of them (see pp 64-5)—will have to ask themselves this question and decide to what extent the Minister's letter modifies the position."

DIET AND LIVER DISEASE

In reviewing our present knowledge of the significance of nutritional factors in the causation and treatment of liver diseases Prof L J Wits has successfully accomplished a formidable task. In two short articles, published on page 45 of this number and on page 1 of last week's issue, he has covered most of the important experimental and clinical developments in this field and has brought together much valuable information from widely diverse sources. It is obvious that considerable differences exist between the types of liver disease produced artificially in experimental animals and those most familiarly known in human subjects, at the same time the lesions found under experimental and clinical conditions are often sufficiently similar to make their comparison instructive.

The infiltration of the rat's liver with excess of fat, which is taken by Wits as a starting-point in approaching his subject from the experimental side, has been well known to nutritionists for many years. The fat content of the liver may readily be increased tenfold or more by including much fat in the diet and simultaneously withholding substances which facilitate the dispersal of fat from the liver. These "lipotropic" agents include choline, a constituent of lecithin, and methionine, an amino-acid containing sulphur which is present in casein and other proteins of high nutritional value. More recently it has been found that the livers of animals kept for some months on a diet which produces fatty livers eventually develop cirrhosis usually with the formation of a brown pigment known as "ceroid".¹ Since in this country the scarcity and high price of spirits has practically eliminated alcohol as a cause of cirrhosis, it is interesting to speculate whether the 2,000 cases which are usually in process of dying from this disease can be due to nutritional deficiency. Wits points out that while the position in England is uncertain there is ample evidence that liver diseases are associated with faulty nutrition in the Tropics. Thus fatty infiltration of the liver occurs in "kwashiorkor," or malignant malnutrition,² a disease which is common in grossly malnourished African natives. Cirrhosis of dietary origin is common in children in India, Ceylon, and China.

¹ Lillie R D, Daft F S and Sebrell W H. *Publ Hlth Rep Wash* 1941 56 1255

² *British Medical Journal* 1946 1 958

Focal necrosis of the liver is another lesion caused by deficiency of protein in rats, its onset being sudden rather than gradual as in the development of cirrhosis. The missing nutrient here appears to be cystine, another amino-acid which contains sulphur. Cystine, unlike choline and methionine, has no lipotropic action, and its addition to the diet in excessive amounts appears to favour the development of cirrhosis. Witts reminds us that sulphhydryl groups are concerned in the vital enzyme systems of the liver, which may explain why liver cells deprived of cystine and methionine should become unduly vulnerable to the toxic action of chloroform, carbon tetrachloride or arsenical drugs. The whole story of the relation of liver damage to diet, however, appears to cover a wider field. Though dosing with sulphur compounds before or very soon after anaesthesia with chloroform is effective in preventing liver damage in suitable circumstances, it is clear that under other conditions widely different substances may be equally effective. Thus the increased vulnerability to toxic agents due to starvation may be checked by giving carbohydrate.

Information obtained from animal experiments and the application of it to the benefit of human sufferers from liver disease appears to favour the maintenance of sound general nutrition rather than the extensive exploitation of choline, methionine, or cystine as drugs. In regard to cirrhosis better results are obtained by giving a good diet rich in protein rather than by attempting to lighten the work of the liver by giving a diet high in carbohydrates. Treatment with methionine and choline, according to Morrison,³ is beneficial even when the diet is already rich in protein, but the experience of other workers has been less convincing. Acute necrosis of the liver in the human subject is a much rarer disease than cirrhosis and must be diagnosed with care. It is not surprising, therefore, that our knowledge of its dietary treatment should be scanty. In the present state of doubt the clinician may well concentrate on the relief of shock with fluids, glucose, and milk, though the analogy with experimental liver necrosis suggests that research on the value of proteins and amino-acids might be well rewarded. On the other hand infective hepatitis, in common with the closely similar homologous serum jaundice and post-arsenical jaundice, appears to have no parallel in the experimental animal. However, in recent years opportunities for clinical research, particularly among troops, have been all too frequent. The results of treatment with relatively small doses of choline, methionine, and cystine have on the whole been unconvincing, and in view of the benign nature of the disease the intravenous injection of the large doses calculated to be necessary from the results of animal experiments seems quite unwarrantable. Witts advises a light diet with plenty of partially skimmed milk, but considers that it does not matter much what the patient eats provided he keeps on eating. An interesting point, which appears to emphasize the importance of diet in infective hepatitis, was noticed during the war: poorly nourished coloured troops, though relatively free from the disease, had, when once infected, a much higher mortality rate than that of white troops.

While therefore we have considerable knowledge of the specific nutritional factors concerned in the production and

prevention of liver diseases in experimental animals, we can still only recommend that human liver diseases should be treated by a diet which is generally sound, wholesome, and otherwise suitable. Possibly this gap between theory and practice may be explained by the fact that experimental knowledge, though extensive, is still far from complete. The study of experimental liver disease is indeed complex. Thus excess of fat, excess of cholesterol, imbalance of vitamins of the B complex, and even starvation all tend to increase the fat content of the liver. Choline, protein, methionine, the cyclic alcohol inositol, and the pancreatic hormone known as lipocaic are among the substances having lipotropic action, but they are effective in different degrees according to the factors tending to cause the fatty infiltration. Recent work has suggested that the situation may be complicated by the interplay of many other substances. Dam and Kelman,⁴ for example, have claimed that in certain circumstances vitamin E has the same action as inositol, and that it appears to be necessary for the formation of lipocaic. In the production of cirrhosis certain fats are more active than others, and cod-liver oil in particular seems to promote the formation of ceroid pigment.⁵ On the clinical side, moreover, further complications may arise through the secondary effects of disease. Thus the metabolism of vitamin A, stored mainly in the liver, is disturbed by both acute and chronic human liver diseases and in cirrhosis the reserves are often completely exhausted.^{6,7} We are faced therefore, with a complicated network of interrelated biochemical systems for the unravelling of which prolonged and intensive research will undoubtedly be necessary.

THE MEDICAL OFFICER OF HEALTH

In January, 1847, the first medical officer of health in this country took up his appointment. The event was one which had far-reaching effects on the health of the country, and the occasion warrants a brief survey of the circumstances which led up to the appointment and to the results which have been achieved in the field of public health during the last hundred years, discussed elsewhere in this issue.

The starting-point of all our health measures was the cholera epidemic which swept this country in 1831-3. In his *English Sanitary Institutions* Sir John Simon says that its importance "lies chiefly in the circumstance that, during the alarm, many intelligent persons throughout the United Kingdom had occasion to become more critically cognizant than they had ever before been of the sanitary conditions under which the mass of the people were living." Despite the grievous losses occasioned by the cholera, it was not immediately recognized that the Boards of Health which were set up at the time need be anything but temporary institutions. The period between 1834 and 1845 was marked by the labours of Edwin Chadwick in calling attention to the sanitary conditions of the labouring population and in demanding their redress. 1838 saw the issue of the valuable report by Southwood Smith *On some of the physical causes of sickness and mortality to which the*

⁷ Moore T. *Biochem. J.* 1937 31 155

poor are particularly exposed, and the Royal Commission on the Health of Towns reported in 1844 and again in 1845. Many medical men appreciated that official action would be necessary in order to reduce the mortality which resulted from the prevalent conditions, and it must have been realized by some that what was wanted in each industrial area was the specific appointment of a doctor to co-ordinate the work of prevention which had been shown to be so necessary. It is a significant fact that fifteen years were to elapse between the beginning of the cholera epidemic and the appointment of the first medical officer of health.

Of the men who were active in provincial cities in pointing out the need for sanitary reform few were better known than William Henry Duncan, of Liverpool. Born in 1805, he was Physician to the Royal Infirmary, Lecturer in Medical Jurisprudence in the Medical School, and from 1837-41 he was President of the Liverpool Medical Institution. In 1843 he published the text of two lectures in which he pointed out that the average age at death in Liverpool, Manchester, Leeds, and Bolton was 19 years, and that 20% of the population of Liverpool lived in cellar dwellings. In 1845 he was the principal speaker at a public meeting for the purpose of establishing a Liverpool Branch of the Health of Towns Association. In 1846 the Town Council of Liverpool procured the passing of three private Acts, the third of which—the Liverpool Sanitary Act—empowered the Council to appoint “a legally qualified medical practitioner, of skill and experience” as “the Medical Officer of Health for the Borough of Liverpool.” It was almost inevitable that Duncan should be offered this appointment. He accepted on a part-time basis, and his duties began on Jan. 1, 1847. In the following year his salary was raised to £750 per annum, and he became a whole-time officer. Duncan’s work in Liverpool is worthy of the highest praise. In the year of his appointment there were 5,845 deaths from “fever” and 2,589 from “diarrhoea” in Liverpool, and in 1849 the population of 300,000 suffered 5,245 deaths from cholera. Duncan laboured for the provision of hospital beds, and for facilities to enable the district medical officers to visit the patients. In three years he reduced the percentage of the population living in cellar dwellings from 12 to 2, and in the 16 years of his official work the death rate in the city fell from 39 to 27 per 1,000. Sir John Simon said of him that “with the ungrudging confidence and support of a very public-spirited local authority he established methods of work, and initiated courses of improvement, which have continued to the present day.”

The sequel to Liverpool’s pioneer effort is better known. In 1848 the Corporation of the City of London secured the passing of the City Sewers Act, which empowered it to appoint a medical officer of health. It is interesting to note that the duties and functions of this officer are set out in the Act in terms which are practically identical with those used in the Liverpool Act. John Simon was appointed to the post at the age of 32 years, and he held the office until he was made the first medical officer to the general Board of Health seven years later. In 1855 medical officers had to be appointed to the various vestries and district boards in London, and the Public Health Act of

1872 required every provincial sanitary authority to appoint a medical officer of health. In this way the appointment of professional health officers throughout the country was at last established—forty years after the inroads of cholera had directed the attention of enlightened members of the public to the necessity for some such measure.

Sir Allen Daley, who has himself been a medical officer of health for the long period of 35 years, has dealt sympathetically and authoritatively with the story of the health officer in his presidential address to the Society of Medical Officers of Health. In comparing the important statistics for 1847 and for 1945 respectively he points out that, though the birth rate has declined by almost half, the death rate has fallen from 24.7 to 11.4 per 1,000, the infantile mortality rate from 164 to 47 per 1,000 live births, and the maternal mortality rate from 4.52 to 1.84 per 1,000 live births. These are striking figures, and they should not be obscured by the fact that the statistics for certain conditions which are more prevalent in later life—and which were incidentally much more difficult to diagnose correctly in 1847—have shown a marked increase. Nevertheless, these adverse statistics occur as pointers to the directions in which research and improved administrative measures are most likely to achieve successful results.

The Medical Officer of Health has never been the most lauded member of the medical profession. The title in itself is cumbersome and does not describe his work accurately. Presumably the Liverpool Corporation of 1846 was responsible for coining the title, though the influence of Whitehall cannot be excluded. In any event, the unfortunate choice had come to stay. Weighted during each successive decade with increasing administrative responsibilities, with staffs grown to proportions sometimes almost unmanageable, he has developed into a professional administrator with the heaviest of responsibilities—that of the health of his fellow citizens. In such conditions most of our distinguished officers have continued to retain the scientific outlook, and many have added to the sum of knowledge. Perhaps never in their long career have the virtues of the Medical Officer of Health received such spontaneous recognition from the public at large as during the late war, when bombing led to conditions which were apparently so conducive to the spread of infectious disease. The spontaneous gratitude which was often then expressed by members of the public was a source of gratification to hard-worked heads of health departments.

The period between 1930 and the present day has been one of much increased responsibility for the medical officers of health of large hospital authorities. Under their guidance, and frequently their active administrative control, the municipal hospitals have been altered beyond recognition. Now, under the provisions of the new Act, these responsibilities will pass to the officers of Regional Authorities, but the chief health officer of the area will probably have other onerous duties placed on his shoulders.

Perhaps the chief danger besetting the M.O.H. is that he may see administration as an end in itself and not as the means for helping the individual citizen, but despite criticisms of their work in detail—sometimes deserved—medical officers of health have made substantial contributions to the nation’s well-being.

A FORETASTE OF CONTROL?

That determined opponent of administrative medicine, Dr Foxell, of Birmingham, gives, through the courtesy of Sir Ernest Graham-Little, a further illustration in this week's correspondence columns of the awkward situation in which the administrator places himself (or herself) in attempting to intervene in the treatment of the individual patient. It must, of course, be recognized that the Ministry of Food in times of shortage has to see that available supplies are evenly distributed and that no unfair discrimination is made in the case of any one member of the community. It is recognized, too, that categories for favoured treatment must be drawn up and that there must be some guiding rules for the extent to which extra allowances can be granted. To criticize the recent action of the Ministry of Food is not to ignore the valuable work done by it under the initial inspiration of Lord Woolton during the war years. But the writers of two letters criticizing the view expressed in the annotation in the *Journal* of Dec 28 seem to us to have missed the principle at stake. It is almost unnecessary to say in these columns that the extra fat demanded by Dr Foxell for his patient would not have saved the patient's life—Dr Foxell believed it would prolong it. The practice of medicine is first and foremost a humane art, and the doctor treating a sick person does not treat a disease but an individual. Let us recall the facts once more. Dr Foxell's patient with carcinoma of the oesophagus was, on expert advice, given a certain diet in hospital which included two ounces of fat a day in the form of butter or margarine. When he was discharged from hospital this regime was continued on the grant by the local Food Office of the extra fat. The details were then sent from the local Food Office to the Ministry of Food, and the medical advisers, when consulted, quite properly gave the Ministry an impersonal assessment of the case. Armed with this, the Parliamentary Secretary to the Ministry of Food gave an impersonal ruling, and the patient—a person—is deprived of what his own doctor has considered to be necessary for him. We do not question the good faith of the administrators, but did they for one moment stop to consider the state of mind of a man who probably knew he was doomed to die and who therefore clung to every chance of prolonging what little life there was left to him? Here was a sick person who had been carefully and conscientiously treated in hospital and who had been receiving a certain diet as the result of a full consideration of his case by the medical men directly responsible to him. When his regime was rudely interrupted by administrative interference what must that patient have thought first of all of his own doctors, and secondly of the State, whose function it is to safeguard the rights of the individual? Dr Back, in his well-argued letter, seems to miss the point that the patient had been granted the increased fat recommended. The situation would have been different if he had not received the extra ration. But as he had received it the intervention of the State must first of all make him lose confidence in his medical advisers, and for the State to do this to a dying man would seem to us to be grossly inhuman.

What has worried thoughtful medical men during the past years' discussion on a National Health Service has been this very question of interference of the State with what is called the doctor-patient relationship. Some sceptics have believed that this was a mere slogan, and those in our own profession who have believed this have usually not been practising doctors. Dr Foxell's case expresses better than anything else what this doctor-patient relationship is and what happens when the State, through well-meaning persons who have never seen the patient, interrupts a regime of treatment. If this can happen here and now, what will happen when the medical profession is nationalized and the responsibility of every doctor is divided between the State and his patient—with the State as paymaster?

Dr Foxell's further illustration in this week's correspondence columns once more shows the dilemma of the administrator who tries to treat a sick person. The details are there for all to read. What conclusions can be drawn from them? The Ministry's medical advisers are eminent, high-minded men, widely respected by their professional colleagues. They have done no more than give the Ministry of Food the correct examination answer to a question, and for this, if it may be said without undue flippancy, they deserve full marks, but, as in the case of all answers to examination questions, the answer must be incomplete because the one essential piece of evidence is missing—namely, the patient himself. No sick man or woman or child can be treated on textbook lines. The clinician's job is to treat a person, and this cannot be repeated too often. Even Dr Watson, Sherlock Holmes's professional colleague, would have regarded such a statement as elementary.

RINGWORM OF THE FEET

It would be a diverting exercise to consider the many different treatments of foot ringworm during the last thirty years. Few have outlived the two established favourites. Whitfield's ointment and Castellani's fuchsin paint. Ringworm of the feet was recently a matter of consequence to military efficiency, because though a minor affection it can become sufficiently disabling to incapacitate. Experience gained in war medicine does not always advance civilian practice, but treatment of parasitic diseases provides an exception to this generalization. A contribution¹ from Johns Hopkins Hospital on sodium caprylate in the treatment of dermatomycosis of the feet is a case in point. A complementary paper² shows the frequency and significance of this form of ringworm in North America. (We have recently³ commented on other American work on the treatment of fungous infection of the feet.)

Of 871 entrants to the U.S. Naval Academy evidence of foot ringworm—peeling of the skin, fissures, or maceration—was present in 59.9%, corresponding to figures⁴ of the incidence among male entrants to California University in 1928. Of the naval cadets 17% who were clinically negative gave positive results on direct microscopical examination. This suggests they might be carriers, or persons in whom

the fungus will become active only under environmental changes—an observation throwing new and perhaps disconcerting light on the prophylaxis and treatment of *uneped*

The paper by Edmund L. Keeney and his colleagues¹ on sodium caprylate arose out of observations on its effectiveness against *Monilia albicans*. The fungistatic effects tested by the agar cup-plate technique of Ruehle and Brever showed remarkable inhibiting action on the causal trichophyton, and an associated incomplete bacteriostasis of streptococci and staphylococci. For the clinical investigation at the US Naval Academy ninety-one midshipmen with foot ringworm, confirmed by laboratory tests and culture, were divided into two groups, forty-six were treated with sodium caprylate ointment, forty-five acted as controls. Direct examination of the treated group gave 27.5% after two weeks and 9.3% after four weeks with slides showing the trichophyton, or 90.7% entirely free from the fungus. The later records were less satisfactory: after five and six weeks' treatment 14.2% and 12.8% positive slides respectively were obtained, due to a tendency to the irregular use of the remedy after the first enthusiasm and the clinical aspects had declined. This result must have meant that some of the 90.7% symptomless were either reinfected or not entirely free from the fungus. The authors' belief that the ointment, the formula for which is given below, provides a new and improved method of treatment is supported by their published results.

Sodium Caprylate Ointment

Caprylic acid	10.00%
Sodium hydroxide (90% of theoretical amount required)	2.45%
Diethylene glycol mono-ethyl ether	3.00%
'Carbowax (6000)'	47.50%
n-propyl alcohol	10.00%
Zinc caprylate	5.00%
Water	22.05%

Note—10% of the above caprylic acid is left free for a final pH adjustment to 8.0

METABOLISM AND THE LIVER IN "MEDICAL SHOCK"

In an interesting paper Davidson and his colleagues¹ report studies on "peripheral vascular failure," by which they mean apparently "states of low blood pressure." Their cases include such varied conditions as pneumonia, pericarditis, myocardial infarction, and barbiturate poisoning. They found that the blood sugar was raised, as was the lactic acid of the blood, while the bicarbonate reserve was lowered. The alpha amino-acid nitrogen of the blood was often elevated, and there was sometimes considerable azotaemia. The prothrombin time was lengthened, and there was often a slight rise in the icterus index. In the fatal cases there was usually some change in the liver, such as focal necrosis and degeneration, especially in the centres of the liver lobules. Blood alpha amino-acid nitrogen does not normally rise with increases in nitrogen metabolism, but if the recognized increased nitrogen catabolism of peripheral vascular failure is associated with a failure of deamination due to impaired liver function, then an increase in alpha amino nitrogen might be explicable.

From the same school there had previously been reports of similar biochemical changes in cases of burns and in haemorrhagic shock, anoxia, and acidosis.² In a severe

case of burns the blood sugar may reach as high as 300 mg per 100 ml. These patients, however, are sensitive to insulin, and when more glucose is given it seems to be normally metabolized. An increase in protein catabolism and gluconeogenesis from protein was thought to be possibly responsible for this rise in blood sugar. Alpha amino nitrogen is an intermediate product in gluconeogenesis from protein, but it does not normally accumulate in the blood as it is easily dealt with by the liver.

These changes then are all secondary consequences of anoxia or of a depressed circulation, particularly when associated with low blood pressure. A good deal of attention has been given in America to the contribution these metabolic disturbances may make to the morbid process of shock. It is well known that when some cases of haemorrhagic shock have gone on too long with a low blood pressure they may not recover despite apparently adequate transfusion, at this stage they are said to be "irreversible." The recognition of profound metabolic disturbances associated with liver damage in shock in animals and in man led to the idea that these biochemical changes might be an important factor in the "irreversible state."³ This hypothesis has been put to the test by Frank, Seligman, and Fine.⁴

If bled dogs are kept with a blood pressure down to 30 mm Hg for sufficiently long they will certainly die even if transfused. Frank and his colleagues arranged that such dogs should be *vivi-perfused* by cross-circulation from donor dogs without raising the blood pressure of the recipient. Blood from the carotid artery of the donor dog was led into a recipient vein through a pressure-reducing valve, while blood flowed from the femoral artery of the recipient into the femoral vein of the donor as soon as the recipient's arterial pressure rose above 30 mm Hg. By connecting the donor dog's artery to the splenic vein a rich arterial blood supply was assured to the liver, though otherwise the animal was still "shocked." Of 12 dogs whose livers were thus maintained 11 survived when transfused after a period of shock ordinarily long enough to render transfusion ineffective. Of 17 dogs similarly treated except that the donor's blood entered the jugular vein 15 died after late transfusion. This seems to demonstrate clearly that loss of liver integrity is a significant factor in the collapse of the organism in advanced haemorrhagic shock and that the preservation of liver function is of crucial importance in recovery.

These experiments gave Frank and his co-workers an opportunity to investigate the part played by biochemical changes in contributing to death from shock. Disturbances in intermediary metabolism were less marked in shocked dogs being *vivi-perfused* than in dogs not so treated but in an equally severe degree of haemorrhagic shock. The presence of a healthy liver did not completely prevent the development of these metabolic changes, and it therefore seems unlikely that they contribute specifically to the fatal issue. The exact way in which the liver protects the organism against "irreversible shock" is not clear, but disturbance of some unrecognized "detoxicating" function is a possibility.

These experiments render unlikely the hypothesis previously suggested by Wiggers and Werle⁵ that "irreversibility" is brought about by heart failure from prolonged depletion of coronary flow. They also make a weighty contribution to the problem of low blood-pressure states and bring a deeper understanding of the final mechanisms common to a variety of different types of circulatory failure.

William Henry Duncan (1805-1863)

A PUBLIC HEALTH CENTENARY

On Jan 1, 1847 Dr W H Duncan was appointed by the City of Liverpool as the first salaried medical officer of health in Great Britain

The interest of the State in the physical health of its citizens is a comparatively modern development. It dates from the early nineteenth century and broadly speaking may be traced to three causes. Throughout the country there was an increasing reaction against the anarchy of the Industrial Revolution. There was also the steady development of a humanitarian spirit, as evidenced by John Howard's work on prison reform, the agitation for the abolition of the slave trade, and the attempt by Sir Samuel Romilly and others to infuse some humanity and common sense into the old penal laws. To these two general trends was added a clear threat. Asiatic cholera had appeared for the first time in Europe and had spread to England.

This prompted the setting up of the Consultative Board of Health in 1831. Its advice however was no more useful than that of the College of Physicians at the time of the Great Plague and it was soon superseded by the Central Board of Health which was almost equally impotent. More important than either of these short-lived bodies was the Central Poor Law Commission which was set up in 1834 and more important than the Commissioners was their Secretary, Mr Edwin Chadwick.

Chadwick believed that pauperism was largely connected with disease and that the Poor Law Commissioners must largely concern themselves with questions of communal health. He therefore persuaded Dr Southwood Smith to conduct an inquiry in 1838 into an outbreak of fever in the slums of Whitechapel. The next step was a long medical report again instigated by Chadwick and prepared by Dr Southwood Smith on the causes and effects of "Fever in Twenty Different Metropolitan Boroughs and Unions". There followed in 1840 an Act authorizing under the control of the Poor Law Commission free vaccination against smallpox. Two years later the Secretary to the Commissioners made his classic "General Report on the Sanitary Condition of the Labouring Population" of Great Britain. This document of which 10 000 copies were published, forced into public prominence the part played by sickness and

ill-health in the production of poverty and insisted that the prevention of disease was one of the first duties of the State. It led to the appointment in 1843 of a Royal Commission, with the Duke of Buccleuch in the chair to inquire into the public health generally. The Report of the Royal Commission amply confirmed what Chadwick had already made clear that every where there were defective water supplies and a lack of any kind of sanitation, that the harvest of the slums was too many widows and orphans, a high infantile mortality and a low expectation of life, so that 'the loss of working ability among large classes cannot be less than 8 or 10 years'. Legislation followed, and in 1848 the General Board of Health was established for a first term of five years when what had been known as the Health of Towns Bill became the first Public Health Act.

Meanwhile the City of Liverpool had moved one step ahead of the rest of the country in creating the appointment of which the centenary is now being celebrated. Under a Private Act of 1846 Liverpool appointed Dr William Henry Duncan, an Edinburgh graduate, as the first salaried medical officer of health in Great Britain. He took up his duties on Jan 1, 1847, at a salary of £300 a year.

The Corporation of the City of London followed the lead given by Liverpool. Dr John Simon became London's first medical officer of health in 1848. John Simon was later to take over the task begun by Edwin Chadwick. The General Board of Health had its statutory five years of life. At the end of this time the Government of the day was defeated on a Bill intended to renew the existence of the General Board. The very qualities which had distinguished Mr Chadwick and made him so effective an administrator had also made him and the Board extremely unpopular.

The Board was reconstituted without Chadwick and in 1859 a Medical Department under the Privy Council was established. This was the reaction against bureaucracy, or rather, against the bureaucratic despotism which Chadwick was held to personify. This new Department continued to act under the skilled guidance of Sir John Simon until the formation of the Local Government Board in 1871. The Local Government Board replaced the Medical Department and the Poor Law Board and continued the functions of both as the principal central authority for public health until the creation of the Ministry of Health in 1919. Clearly, then, all the earlier developments in public

Sir John Simon (1816-1904)

health legislation and practice in this country branched from the work of two outstanding individuals—Edwin Chadwick and John Simon

Edwin Chadwick was born at Longsight, near Manchester, on Jan 24 1800, just four years after Dr Percival and Dr Ferrar and their friends had set up the Manchester Board of Health, a voluntary society intended to deal with factory hygiene and to bring before Parliament the urgent need for reform and regulation. He was educated for the Bar, but his essays in the *Westminster Review* on different methods of applying scientific knowledge to the business of government brought him to the notice of Jeremy Bentham, who engaged him as a literary assistant and ultimately left him a handsome legacy. In 1832, the year of the great Reform Bill and the year in which Charles Hastings founded the Provincial Medical and Surgical Association, Chadwick was employed as an investigator by the Royal Commission on the Poor Law, and a year later he was made a full member of that body. With Nassau W Senior, the Oxford Professor of Political Economy, he drafted the report which procured the passing of the Poor Law Amendment Act of 1834. His special contribution was the institution of the union as the area of administration. He favoured, however, a much more centralized system of administration than was adopted, and complained often that the reform of 1834 was badly marred by the rejection of his scheme, which involved the management of poor law relief by salaried officers centrally controlled with the board of guardians acting only as inspectors. The country and the Government rejected Chadwick in 1854. Recognition of the value of his work came only towards the end of his long life. He was made K C B in 1889, and he died at East Sheen, Surrey, on July 6, 1890. He had given public health administration a series of clear-cut objectives by showing how the census and bills of mortality could be used to diagnose those public ailments which required for their control various public health measures.

Sir John Simon was born in London on Oct 10, 1816. In the spring of 1844 he was awarded the first Astley Cooper prize for a physiological essay on the thymus, and the following year he was elected FRS. He was appointed lecturer on pathology at St Thomas's Hospital and subsequently became a surgeon on its staff. He published many clinical surgical lectures and might easily have become well known as a surgeon had he not elected to serve sanitary science in the City of London in 1848. His most notable book was *English Sanitary*

Sir Edwin Chadwick (1800-1890)

Institutions which among other things pointed out that before the passing of the Medical Act of 1858 there were 'Twenty one disconnected corporate Authorities within the United Kingdom using their heterogeneous credentials of qualifications (more or less) for responsibilities in Medicine'.

It was Simon who described preventive medicine as 'the province where Medicine joins hands with Common Sense' and who most appreciated the work of Chadwick in establishing preventive medicine in Great Britain. Sir Edwin Chadwick he wrote, 'was the first to awaken our statesmen of those times to the duty of caring for the Public Health, and the first to bring Health under the protection of the Law'.

Thomas Southwood Smith (1788-1861)

NUTRITION IN VIENNA

Dr HARVEY S COLLINS an American nutrition expert addressed an Unrra conference in London recently on conditions in Vienna. On arrival there in April, 1946 he found the people listless, but in the following June their spirits appeared to be greatly improved a circumstance which seemed inconsistent with the official ration and the known decrease in food obtainable off the ration. He therefore made a survey of a statistically representative sample of the community selected at random. Some 10 000 people in all consumer groups were invited to come for medical examination, and some 7,500 did so, while visits were made to the homes of those who did not attend to find out whether they were prevented by illness, 2,000 dietary histories were taken. The results of the medical survey showed retarded growth in children, particularly in the 7-13 age-group. Adults over 40 were under weight, the degree of deterioration increasing with age. On the other hand, there was not much evidence of malnutrition. Oedema of the ankles was present in a number of individuals, but in all but 0.3% could be accounted for by varicose veins, heart disease, or other ailments. In the 0.3% the condition was consistent on medical history and examination, with protein or calorie deficiency, and was the so-called 'famine oedema'. Clinical evidence of deficiency of vitamin B complex was rare. 0.8% showed signs suggestive of riboflavin deficiency. Scurvy was not found in any case but vitamin C deficiency was suggested in 0.62%, and vitamin A deficiency in 0.71%. There was little evidence of the vitamin D deficiency in young children which was so marked after the First World War. The improvement was presumably due to preventive measures in the form of distribution of cod-liver oil and other vitamin sources and preferential milk distribution.

Dr Collins summed up the state of nutritional health of the people of Vienna in the summer and early autumn of 1946 as maintenance at a level below normal but not at such a low level as would constitute actual nutritional disease. The allocation of food to the city had been the smallest in any large European community during 1946. In spite of this the medical catastrophe which might have been expected had not happened, probably because the average citizen had managed to secure extra food through channels outside official distribution such as factory meals of more value than the coupons surrendered voluntary society contributions and produce obtained from gardens or farmers, or from the black market. These sources might be expected to diminish during the winter, but in part this would be compensated by a recent increase in the ration to 1 550 calories. The maintenance of this standard, with the winding up of Unrra would be the responsibility of the Austrian Government and the Occupying Powers.

FINAL RESULTS OF THE PLEBISCITE

The following tables show the results of the plebiscite up to and including Jan 6 1947

MEDICAL NEW YEAR HONOURS

The names of the following members of the medical profession were included in a New Year Honours List published in the *London Gazette* on Jan 1

Knighthood

Major-Gen HUGH CLIVE BUCKLEY CSI, FRCSed, IMS Principal (retired), Medical College, Agra United Provinces
CHARLES ERNEST HERCUS, DSO, OBE, MD Professor of Bacteriology and Preventive Medicine, University of Otago, and Dean of the Medical School
EARDLEY LANCELOT HOLLAND MD FRCP, FRCS Past President of the Royal College of Obstetricians and Gynaecologists

C.B (Military Division)

Surgeon Rear-Admiral HERBERT RICHARD BARNES HULL MRCS L RCP, RN Honorary Surgeon to the King
Major-Gen EVELYN ALEXANDER SUTTON CBE, MC MRCS L RCP late R.A.M.C.

C.M.G.

PATRICK ALFRED BUXTON, FRS, MRCS, L RCP Professor of Entomology in the University of London and Director of the Department of Entomology, London School of Hygiene and Tropical Medicine

MELVILLE DOUGLAS MACKENZIE MD Principal Medical Officer in charge of epidemiology and international health, Ministry of Health

ALBERT RAY SOUTHWOOD MD MS Chairman Central Board of Health State of South Australia

C.I.E.

Major FREDERICK AUGUSTUS BERRILL SHEPPARD, OBE, FRCSed, IMS Surgeon Government General Hospital, and Professor of Surgery, Medical College Madras

Lieut.-Col WILLIAM JOSEPH WEBSTER MC MD, IMS Senior Assistant Director Central Research Institute Kasauli and Officer in Charge Serum and Vaccine Section

C.V.O.

DANIEL THOMAS DAVIES MD FRCP Physician to HM Household

FRANK ANDERSON JULER FRCS Surgeon Oculist to HM Household

C.B.E (Military Division)

Acting Air Commodore HENRY OSMOND CLARKE FRCS R.A.F.V.R. Consultant in Orthopaedic Surgery, R.A.F.

C.B.E (Civil Division)

ELDRED CURWEN BRAITHWAITE OBE MSDurh FRCSed Colonial Medical Service Senior Specialist Nigeria

JAMES HARDIE-NEIL DSO, MB, ChB Medical practitioner Auckland New Zealand

O.B.E (Military Division)

Lieut.-Col (Temporary) ERIC FRANCIS EDSON MB ChB R.A.M.C.

Acting Squad Ldr ROBERT ALLISON MOOREHEAD MB BCh R.A.F.V.R.

Major ERNEST SOYSA MB BS Ceylon Medical Corps

O.B.E (Civil Division)

FREDERICK AUGUSTUS LESTRANGE BURGESS MBE MRCS L RCP Post Office Medical Officer for the Hockley and Hands worth districts of Birmingham

PERCIVAL PASLEY COLE FRCS Senior Surgeon Dreadnought Seamen's Hospital, Greenwich

JOHN WILLIAM HAWKESLEY GRICE, MRCS, L RCP British subject resident in China

CURTIS DANIEL JOHNSTON MD, CM Medical Officer Black River District Jamaica

PATRICK WILLIAM ROBERTSON PETRIE, MB ChB For medical services in the Aden Protectorate

PIERRE FRANÇOIS JOSEPH LOUIS RATHIER DU VERGE MC MRCS, L RCP Medical Superintendent, Victoria Hospital Mauritius

JAMES GRAHAM WILLMORE MD, CM Lately Principal Medical Officer, Ministry of Pensions

M.B.E (Military Division)

Major JOHN HENRY COWDREY NZMC

Major (Acting) ROBERT MACFIE MARQUIS MB, ChB R.A.M.C.

M.B.E (Civil Division)

ISAAC BOATENG ASAFU ADJAYE MRCS, L RCP For political and social services in the Gold Coast

ALEXANDER SAMILL FRATER MB, BS For medical and public services in the New Hebrides

LEON GILLIS MChOrth, FRCS Senior Surgeon, Ministry of Pensions

CECIL VERNON JUMEAUX LMS Government Medical Service For services during the enemy occupation of Malaya

CHARLES STUART OGILVY L RCP & SEd L RFP S Glas Civil Medical Practitioner Military Detention Barracks Sowerby Bridge

HUGH WANDS MB ChB Medical Officer Sandakan North Borneo For services during internment

Kaiser-i-Hind Gold Medal

MARGARET GILLESPIE McMILLAN MB ChB In charge of Women's Mission Hospital, Ajmer

An interesting account of Kislovodsk—one of the spa towns in the Russian Caucasus—is given by Alexander Werth in the *Manchester Guardian* of Dec 31. The sanatoria 'are as clean and efficient as anything in Switzerland—and even duller,' and some are 'almost unbelievably luxurious.' The equipment of all kinds seems to be excellent. The spa is dealing with 100,000 people a year—from patients with a variety of ailments to those who simply need a rest—as compared with 150,000 in 1939. There are also a number of men seriously wounded in the war still receiving treatment there. He draws attention to the question of how people are selected for treatment at the spas for the Government attaches great importance to what we should call rehabilitation. Medical boards of Government departments and trade unions select suitable patients not only from the point of view of whether their health will benefit but also regarding their particular value in their jobs. Thus the proportion of directors and important technicians is relatively much higher than that of ordinary workers. Stikharinovites also get preference.

NATIONAL HEALTH SERVICE ACT

PRESIDENTS OF ROYAL COLLEGES AND
MR. BEVAN

We print below correspondence between the Presidents of the three Royal Colleges and the Minister of Health on the National Health Service Act

Jan 2, 1947

My dear Minister,

The opposition of a substantial part of the medical profession to any renewal of discussions with the Government regarding the National Health Service is causing us concern. We fear that it may lead to an impasse and we wish to do what we can to prevent such an impasse arising.

We recognize that certain of the principles of the new Service are incorporated in the Act, but there are other issues of importance which will be determined by regulations, and the form of the Service will depend to a great extent upon what the regulations contain. We feel that there is an opportunity in framing the regulations to meet several of the objections of the profession. Moreover, the implications of some of the proposals for the new Service are not clear to the profession and clarification of these points would be helpful.

We hope therefore, that you will clarify for us any of the points referred to later in this letter on which there may be misunderstanding and that you may be able to give us an assurance that you will endeavour, within the framework of the Act, to meet the views which are held strongly by many practitioners.

Our first point is a general one. We believe that behind the opposition of members of the profession is the fear that to enter into discussions would compromise their position by implying their approval and acceptance of the main provisions of the Act.

In the general practitioner part of the Service there are three points on which we think that some statement from you would be helpful.

The first is the method of remuneration. This is left to be dealt with by regulations, and is therefore presumably open for discussion, but you have made clear your preference for a basic salary, apparently making it generally applicable because of your difficulties in particular cases. There is general agreement that there are circumstances in which a basic salary or a guaranteed minimum may be necessary, but this is not regarded as justifying a universal basic salary. Cannot the circumstances in which a basic salary is appropriate be left open for discussion?

Secondly, a large element in the opposition of some practitioners is the fact that if the Tribunal recommend the expulsion of a practitioner from the Service, his appeal is to be judged by the Minister who has appointed two of the three members of the Tribunal. Neither the words nor the spirit of the Act prevent you from agreeing to seek the advice of the General Medical Council on every such appeal.

In the third place there is a widespread and not unfounded fear that there will be serious interference with the liberty of movement of general practitioners. It would be useful if you would explain how you anticipate that this part of the Act will work in practice, with particular reference to partnerships and groups.

Among specialists there are also certain points giving rise to anxiety. In the background, just as in the case of the general practitioners there is the general issue of the freedom of the profession and the availability to the people of independent medical advice. The whole profession regard it as essential that independent practice should continue and that independent practitioners should have the necessary facilities for the treatment of their patients. We were therefore glad to receive from the Lord Chancellor and from yourself assurances that independent practitioners would be free to remain in attendance on their patients when admitted to the private wings of hospitals, and also to learn that consultants holding honorary positions on the staffs of hospitals would be at liberty to use all the facilities provided. You know our anxiety to induce specialists to do practically all their work within the precincts of hospitals, it is because of this

anxiety that we stress these points. Any information you can give us on the practical operation of the consultant and specialist part of the Service will be helpful.

We hope you will forgive us for intervening, but we feel that the importance of the cause justifies this step.

Yours sincerely,

MORAN,
President Royal College of Physicians
ALFRED WEBB-JOHNSON,
President Royal College of Surgeons
W GILLIATT,
President Royal College of Obstetricians
and Gynaecologists

MR. BEVAN'S REPLY

Jan 6, 1947

My dear Presidents,

Thank you for your letter. I agree with you that an impasse between the Government and the medical profession would be a grave misfortune. I believe that some at least, of the opposition on the part of the profession to discussions is due to a misunderstanding of the proposals, and I am glad to answer any questions if by so doing I can make clear what is in doubt.

You say that some members of the profession fear that discussions would compromise their position by implying their approval of the main provisions of the Act. There is no ground for such a fear. Every doctor will have to decide for himself when the proper time comes whether or not he should take part in the new Service, and the profession as a whole will be free to determine their views on the Service when they know what it is to be. The resumption of discussions now would not prejudice these eventual decisions.

As you rightly point out the ultimate form of the Service will largely depend on regulations which have now to be framed. The issue for the medical profession to day is not therefore, whether they will join a service the final shape of which cannot yet be known, but whether they will accept or forgo the opportunity to influence its shaping. I want to have their help and advice in this task, and I can certainly assure you that, if discussions take place, I shall endeavour to meet any views of the profession which do not conflict with the principles of the Act.

Let me here make one point. It has been said that I have not consulted the profession and that I have been unwilling to negotiate with them. That is not so. While the Bill was in preparation and before Parliament, discussions with the medical profession as with other interests were necessarily conditioned. I could not publish proposals before they were submitted to Parliament and I could not pledge Parliament in advance to their acceptance. Nevertheless I and my officers had full discussions with the Negotiating Committee and were throughout in close touch with the representatives of the profession. Thus the Government were at all stages fully informed of the views of the profession, and the original proposals were modified in many important respects to meet those views. Now the position is different. The Bill is law and within its terms I can negotiate freely.

I turn now to the specific points raised in your letter. You ask three questions about the general practitioner part of the Service.

(i) The Method of Remuneration

Clearly both the method and rates of remuneration are open to discussion since they are matters which are not defined in the Act but have to be determined by regulation. I believe however, that the Government's proposals have been misinterpreted. The Government have accepted the view of the profession that remuneration should be based substantially on capitation fees and have thus rejected the conception of a full salaried Service. I have had in mind that the remuneration of all general practitioners should include an element of salary, but that the element should be small. As you yourselves recognize, there are circumstances in which a guaranteed minimum is necessary, and my own view has been that administratively the most convenient method of achieving this object is to make the basic element universal. But this is essentially a matter which I should like to discuss with the profession.

"Eating well?"

Question that usually gets a wry answer in these days! It's pretty clear that many people are feeling the need of off-the-ration fats and vitamins, because so many of them are taking SevenSeaS. The public is realising that cod liver oil is a fatty food of high calorific value—the only one available in sufficient quantity to make good the cut in the fat ration for example. Moreover, it is the only natural source of concentrated vitamins (A and D) which is both home-produced and plentiful. Luckily, now that our own trawlers have the job in hand again there is plenty of British cod liver oil for all who need it. There is no shortage of SevenSeaS liquid oil or capsules and the transport difficulties which sometimes delayed deliveries are straightening out. Obviously the general food-rationing situation will be difficult for many months yet. But we hope that the burdens it imposes on doctors and nurses will be somewhat lessened, now that it is possible for anyone to buy this supplementary food from the nearest chemist.

STANDARD OIL Vitamin A 20 000 I.U. Vitamin D 2 500 I.U. per oz.
CONCENTRATED Vitamin A 60 000 I.U. Vitamin D 6 000 I.U. per oz.

BY-PASSING

Pronutrin—an enzymic digest of casein—is a natural antacid and a rich source of nutriment. The casein is broken down into smaller units of amino acids and the simpler polypeptides. The amino acids being amphoteric act as buffering agents against stomach acidity. Thus Pronutrin is useful in the treatment of peptic ulcer.

allaying the feeling of hunger and because of its buffering action relieving pain. It provides also the nitrogenous food needed for tissue repair.

Pronutrin may be given in hot cold or iced water combined with meat extract stirred into milk or soup. Literature on request.

(ii) The Tribunal

Here again there is, I think, some misunderstanding. The question to be decided by the Tribunal is whether the retention of a doctor in the medical list would be prejudicial to the efficiency of the Service, and I regard the setting-up of an independent tribunal as an addition to the safeguards which have prevailed under the National Health Insurance for the last 35 years. The function of the General Medical Council is to determine whether a doctor has been guilty of unprofessional conduct, and that remains unaffected. Moreover, a doctor, like any other citizen, has his rights at common law enforceable by the courts and these also remain unaffected. It is not true, as has been so widely said, that doctors in the new Service will be civil servants. On the contrary their full civic rights are preserved unimpaired. I will gladly discuss with representatives of the profession the procedure to be followed before deciding an appeal to me from a decision of the Tribunal to remove a practitioner's name from the list, with a view to providing any additional protection possible within the framework of the Act.

(iii) The Fear of Interference with the Liberty of Movement of General Practitioners

There is no power to direct a doctor to go anywhere or do anything. There is a provision in the Act the sole object of which is to avoid an undue concentration of doctors in any one area. Under this provision a doctor who wishes to practise in the public service in a new area will be required to obtain the approval of a central committee of nine, seven of whom will be medical practitioners appointed after consultation with the medical profession. Normally, however, he will make his arrangements locally through the local executive council, the approval of the central committee being formal. The details of how this will work have still to be discussed and settled. I hope in consultation with the medical profession, but I can say that what I have in mind as the everyday procedure is that in the case of a partnership or group of doctors the partners or members of the group will have the initiative in selecting a doctor to fill an approved vacancy and normally their selection will be confirmed as a matter of course. Similarly in the case of a single-handed practice the initiative in selecting the incomer will lie with the local medical committee. You know, of course, that all doctors who, when the Act comes into operation, are already in practice as principals will have an absolute right to enter the new Service in the areas in which they are practising.

You mention finally in your letter the position of specialists and stress the importance to them of ensuring the freedom of the profession and the continuance of independent practice. It is a basic principle of the new Service that there should be no interference with the clinical freedom of any doctor—specialist or general practitioner. It is also a principle of the Service that independent specialist practice should be free to continue—specialists being free to remain outside the Service or to join it either whole or part time and, if they wish, to be on the staff of a hospital in an honorary capacity. In this way the position of consultants desiring to continue their association with hospitals after the age of retirement and of consultants who do not wish to accept more than a limited responsibility will be met. In the case of a consultant on a hospital staff—and I find it difficult to conceive of a consultant not on a hospital staff—he will be able to treat his private patients in the private beds of his own or other hospitals subject to availability and I recognize with you the need for both public and private accommodation as indeed I have made clear in Parliament on a number of occasions.

The details of all these arrangements will obviously need to be discussed with the profession but I am confident that round a table we shall be able to make satisfactory arrangements which will encourage specialists to work within the precincts of hospitals—a point to which, like you, I attach the utmost importance.

If you think it desirable I have no objection to the publication of this correspondence.

Yours sincerely,

ANEURIN BEVAN

HEALTH CONDITIONS IN THE FACTORIES**A Transitional Year**

The almost complete mobilization for war was relaxed in 1945, a year of dramatic change not only in military and political history but in the industrial life of Great Britain. The process of reconverting industry to the normal peacetime pattern was begun. If swords were not exactly turned into ploughshares, factories turned from producing cannon shells to agricultural implements, from machine-gun parts to roller skates and carpet-sweepers, from parachutes to women's skirts from landing craft to prefabricated houses. Such a reversal involved not only vast mechanical readjustments but equally vast and far more complicated human ones for the six million people who continued in factory employment.

The report of H.M. Inspector of Factories for 1945¹ is therefore of unusual interest. Some comparison is made so far as that is possible—which is not very far—of the industrial conditions of the second world war with those of the first. In 1939–45 safety standards were more generally recognized, methods of dust and fume removal were improved, increased mechanization brought about a lessening of fatigue and in some respects, a lessening of hazard and amenities of a kind undreamed of in the earlier war were provided. Of the relative incidence of occupational diseases poisoning and gassing it is impossible to get a true picture until the extent of the production in the recent war is assessed. The average annual number of cases of carbon monoxide poisoning and poisoning by nitrous fumes was three times greater in 1940–5 than it had been in 1917–18 but in spite of the increased number of cases the fatalities were fewer. For every case of toxic jaundice in the recent war there were more than six cases in the earlier war and for every death there were seven deaths.

Accident Prevention

The number of reported accidents (meaning an accident which is either fatal or disables the workman for more than three days) was just upon 240 000 in 1945 the lowest figure since 1940. Of these accidents 851 were fatal. The general accident rate (37 for every 1 000 persons employed) remains considerably higher than it was before the war, especially amongst boys under 18 (54 per thousand). At the other end of the scale a large number of accidents—generally falls on the level—are sustained by old people who have remained on in factory work. Shipbuilding is an accident-prone industry. 17 667 people were injured in shipyards in 1945. Electrical accidents are gratifyingly few. Of 178 known electrical fatalities in 1945, only 31 were in premises under the Factories Acts. Factory accidents are at a high level in the metal engineering and machinery trades, while the aircraft industry adds another 10 000 of its own. Factory accidents at their present level mean a loss to industry of at least 20 000 workers throughout the year. The appointment of safety officers and committees in factories is attended usually by a reduction in the frequency rate.

General Factory Hygiene

A greater appreciation on the part of both managements and workers of the importance of heating in relation to good working conditions is reported perhaps the stringency of the fuel position has now put the clock back. One of the most difficult problems with which the Factory Department is concerned is the removal of dust and fumes by localized ventilation. A general raising of the standard of ventilation has followed the removal of wartime black-out but the factory worker like other Englishmen abhors a draught. In larger factories air-conditioning plants are coming increasingly into use with good results but trouble from draughts may still arise unless the openings through which the conditioned air is delivered are suitably designed and located. More attention is being given to the quality of lighting as distinct from its intensity—that is to say to distribution, direction, diffusion, colour, avoidance of glare and of excessive contrasts and shadows. Yet greater advantage might be taken of recent advances in illumination technique.

¹ Annual Report of the Chief Inspector of Factories for the Year 1945. Cmd 6992 (London: H.M. Stationery Office).

It is stated that industries are becoming more responsive to new ideas, resulting in more pleasant and therefore generally more healthy working conditions. A great transformation has been wrought by the coming of the canteen. From being a rarity the canteen is now a commonplace in factories of any size. In 1945 there were 11,700 factory canteens, and a few hundred others on docks and building sites, all serving hot meals.

Dr E R A Merewether, senior medical inspector, who contributes a section on industrial health, deals with the occasional criticism that the Medical Branch of the Department pays too much attention to specific occupational risks, to the neglect of measures of general welfare. After all, what are the numbers of cases of industrial disease compared with deaths from pneumonia or with absenteeism caused by the common cold? But he points out that the Factories Act is largely aimed at preventing the common ailments and he instances the provisions as to cleanliness, avoidance of overcrowding, ventilation, washing facilities, protective clothing and the like. The number of colds prevented, the lowering of the incidence of rheumatic diseases, the amount of positive health secured by such means cannot be represented in statistics.

Poisons and Fumes

During the year 45 cases of lead poisoning were reported 2 of which were fatal. It is useful to glance back at earlier years

	Cases	Deaths
1900	1,058	38
1910	505	38
1920	289	44
1930	265	32
1940	108	6

One-third of the 1945 cases were in workers engaged in the manufacture and repair of electric accumulators. The dangers of such work are insufficiently appreciated. Only 5 cases of mercurial poisoning were reported. One death occurred in the manufacture of ethyl iodide and ethyl mercuric chloride, a chemical for agricultural use. In the only other considerable group of cases of chemical poisoning (31 cases) aniline was the responsible agent, these cases were among people engaged in the manufacture of TNT and of nitro and amido compounds of benzene and its homologues. All the 6 cases of toxic jaundice (4 of them women) were due to exposure to TNT.

For the first time there was no case of anthrax arising from wool. Five of the 7 cases reported were workers in hides and skins. Penicillin was used in 6 of the cases, but there is not sufficient evidence as yet to show its relative merits as the treatment of choice in this condition. Epitheliomatous ulceration accounted for 215 cases (all males), 9 of which were fatal. Pitch or tar was the agent in 176 of the cases. There were 94 cases of chrome ulceration, mostly among workers engaged in chromium plating.

The number of cases of carbon monoxide gassing—218, with 18 deaths—shows no lowering on the average of the past six years. The continued high level is ascribed to the large use of power gas, which accounted for 82 of the cases. Instances are given of wrong treatment for gas-poisoning such as the indiscriminate use of aspirin or the mistaken zeal of rescuers in walking the semiconscious victim up and down the factory yard in the fresh air. It is remarked that often the rescuers suffer more severely than the rescued, perhaps because of the physical strain involved. The fact that while there is life there is hope is especially true of carbon monoxide poisoning, one case recovered after 29 and another after 24 hours' unconsciousness.

Carbon dioxide accounted for 1 case of poisoning, sulphur etted hydrogen for 6 cases, sulphur dioxide for 12, chlorine for 47, nitrous fumes for 29, all without a fatality. One death occurred from ammonia gas poisoning and one from benzol. Four cases of anoxaemia are related. 3 of them fatal to illustrate the risk from lack of oxygen in confined spaces. Two of the deaths occurred inside a ship's boiler and the other in a coffer dam 38 ft below deck level. Two recent fatalities, one in a factory make it desirable to call attention to the dangers of di-nitro ortho cresol, which is now in demand for

its fungicidal and insecticidal properties. This chemical exerts its toxic action in industrial operations when it is inhaled in dust or fumes or absorbed through the skin—and it is, of course poisonous when taken by mouth.

Other Industrial Diseases

The reported deaths from silicosis numbered 508 (323 of them in coal mining), and the deaths from pneumoconiosis, asbestosis, and other fibroses of the lung brought the grand total in England and Wales to 1,133, a figure higher than in any year since 1940. In 902 cases of deaths from silicosis investigated during recent years the average age at death was found to be 57.6 years and the average period of employment in the pottery, sandstone, metal grinding or other industry concerned (excluding coal mining) 34 years, 943 other deaths from silicosis with tuberculosis were also investigated, and here the average age at death and the average period in employment were lower by three or four years.

The idea that certain dusts have a protective value in pneumoconiosis was first put forward in 1916 and fresh interest has lately been aroused by the publication by three Canadian workers of the results of treatment of a small number of silicotics by inhalation of aluminium powder. On this the report says:

There is a grave danger that the proved methods of dust suppression and control may be neglected on the supposition that all that is necessary to prevent silicosis is to ensure that a sufficient amount of aluminium or alumina dust is inhaled at the same time as the siliceous dust. At the best it [aluminium dust] can only become an ancillary aid in the prevention of silicosis since the mass effects of inhaling dust in gross concentrations, whatever its nature cannot be neglected.

There was a decrease of over 2,000 in the number of dermatitis cases voluntarily reported (5,996) 'Copra itch,' which has been associated in the past with dockers, affected 8 young women engaged in cleaning and repairing sacks which had been used for copra. There are grounds for thinking that 'copra itch' may be an allergic reaction to a mite containing dust or that it may be more directly initiated by the mites during some phase of the life cycle, the same applies to cheese and grain 'itches.'

Blood examinations have been made on over 500 x-ray workers and workers with radioactive materials, who are described as 'luminizers'. Anaemia was found to be present in about 10% of the luminizers examined but in at least a quarter of these it could be accounted for by circumstances not connected with employment. Slight skin and blood changes were noted in a few cases. A warning is given against the wearing by luminizers of respirators consisting of cotton gauze material backed by an inner layer of lint. All the masks examined were found to be contaminated with radioactive material, and the use of such masks for work with radioactive materials must be discouraged because of this risk, which is accentuated by handling the mask, for example, to facilitate conversation.

At the close of 1945 the number of whole time works medical officers was 143, covering 242 factories, and 903 part time officers gave substantial service in 1,337 factories. The whole time officers have decreased slightly following on the change over to peace-time production, but there are indications that their numbers are rising again. The work of the examining surgeons is the subject of appreciative comment. In 1945 they examined 235,000 young persons for certificates of fitness for employment, and certified 231,000 of them. The principal cause for rejection was pediculosis (1,986 cases) the runner-up being diseases of the skin (496). Rheumatism was the cause of rejection of only 55, and diseases of the lungs of only 129.

A relatively new feature of the work of the department is the setting up of three expert advisory panels, concerned respectively with dermatitis, ophthalmology and radiology. They are composed of consultant physicians and surgeons basically engaged in these branches of work with other experts in the allied sciences. With the co-operation of industrial concerns they have been able to appraise occupational health problems from their several backgrounds and to give the answer to many questions concerning specific lesions, their causes, and means of prevention.

Correspondence

Foretaste of Control?

The following letter was sent to Sir Ernest Graham-Little. We print it by permission of him and the author.

DEAR SIR ERNEST GRAHAM-LITTLE,

I am taking the liberty of writing to you as my university representative in Parliament because I wish you to know of attempts at bureaucratic control by medical advisers to the Ministry of Food interfering between a patient and his doctor. The facts in this particular case are as follows. About two months ago I wrote to the local Food Office (Birmingham), in accordance with the Ministry of Food's regulations (MED 1, p 7). A detailed medical statement, giving full particulars of the applicant's condition and the medical reasons why extra rations are considered necessary. Such a medical statement will be treated as strictly confidential. As a result of this, my patient was granted two pints of milk a day.

On Dec 12 I received from the Food Executive Officer a copy of a letter to him from the Divisional Food Office, London which reads as under

COPY
MD/RA/588

Ministry of Food,
Divisional Food Office
Dec 6, 1946

Dear Sir,

I refer to your letter of Nov 25 regarding application from Mr —, of —, for permanent priority of 14 pints of milk weekly.

Our medical advisers point out that Mr — is entitled to 1 pint of milk per day as a sufferer from chronic colitis and is classed as 2 D of MED 2. Our advisers are of the opinion the pernicious anaemia is completely controllable by modern therapy, and further that the achlorhydria can also be effectively treated. They therefore cannot recommend that any additional priority should be granted other than 1 pint of milk daily in respect of his colitis.

The medical certificate enclosed with your letter is returned herewith.

Yours faithfully,

(sgd) —,
Assistant Divisional Food Officer

To
The Food Executive Officer,
Birmingham C B

The reasons for my advising two pints of milk a day were that besides suffering from chronic colitis, (?) diverticulosis (which incidentally entitled him to one pint of milk) there is almost complete lack of gastric and upper intestinal digestion, due to total achlorhydria. Therefore the only food he can take is milk glucose cheese eggs when available finely minced meat or fish in very small quantities and sieved vegetables. I give you below an example of a typical day's meals.

Breakfast—milk and fine porridge
Mid morning—milk coffee
Dinner—a little very fine mince and milk pudding
Tea—milk tea only
Supper—finely sieved vegetable soup, made with milk and cheese

With these meals he takes as much glucose as he can manage, and it is necessary even on this diet to take from 3 to 6 dr (10.5–21 ml) of dilute hydrochloric acid daily. Nevertheless, his weight has steadily gone down from 11 st 7 lb to 9 st 9 lb (73 to 61 kg). As regards the medical advisers' remarks about the anaemia being completely controllable by modern therapy etc perhaps I should just give you the history.

In 1927–9 (some years before I became his doctor) he developed signs of degeneration of the spinal cord affecting the muscles of the legs and buttocks which became progressively worse until he had a complete paralysis and was hardly able to stand let alone walk. In 1929 in the New Lodge Clinic at Windsor under Sir Arthur Hurst, pernicious anaemia was diagnosed and he was given by mouth what was then the new liver therapy. Later—about 1932—he was I believe the first patient in this country to receive intramuscular liver in the form of campolon. He has had some form of liver therapy continuously ever since then and his blood has been almost normal for some years. However permanent damage had been done which could not be rectified by the most intensive treatment by Sir Arthur Hurst. Considerable wastage and weakness of the lower limbs has persisted. His total achlorhydria has persisted. Unfortunately, in later years he has developed a chronic colon condition.

I resent the implication contained in the letter from the Ministry of Food that I do not understand modern therapy and that my treatment could have been better. I only wish that the late Sir Arthur Hurst were still alive, so that I could pass on this criticism to him. I apologize for bothering you and for writing at such length, but I am sure you will agree that it is an appalling state of affairs when medical advisers who have not seen a patient advise against the patient's own doctor's advice. In this case, it is virtually a sentence to death by slow starvation.

I am,

Yours truly,

HUMPHREY FOXELL

SIR—It may be thought that any stick is good enough to beat the Government with, but I believe that unbiased commentators, who think before they write, will disagree with the implied verdict in the annotation "It Can Happen Here" (Dec 28, 1946, p 995) and with Dr H Foxell's complaint (p 1001) against the Ministry of Food officials for disallowing the extra 12 oz (350 g) of butter beyond the patient's weekly ration. The Ministry's reason for doing so—that no lubricant was necessary for swallowing—is of course fatuous but if they had given as their reason that the patient was suffering from inoperable cancer of the oesophagus and that he was bound to die shortly, I think most sane people would agree that it would be a serious waste of six persons weekly fat ration for a very doubtful and temporary benefit—I am, etc.,

London W 1

WILFRED HARRIS

SIR—From Dr Humphrey Foxell's letter (Dec 28, 1946 p 1001) we see how a patient may be free to choose his doctor but cheated of his treatment.

The doctor on the spot should be free to use his discretion unhampered by control from above and afar and not worried by the letter of the Law. Why, for instance, are only two forms of pneumoconiosis scheduled (Form MED 2, Schedule 1(b), Silicosis or Asbestosis) as needing extra milk ration?—I am, etc.,

London E 6

C JEROME MERCIER

SIR—So much attention has been paid to Dr Humphrey Foxell (Dec 28 1946 p 1001) and his one unfortunate patient who died of an inoperable cancer that I wonder if some could be paid to incurable tuberculous patients whose deaths are far more numerous. At least as good if not a better case than Dr Foxell's could be made for providing these unfortunate people with an extra ration of 2 ounces of butter per day, yet all they have been allowed by the Ministry of Food is 2 ounces of fat per week and 14 pints of milk.

It may be surprising that Dr Summerskill has not been inundated with personal letters demanding extra rations for them, but although in the area where I am tuberculosis officer two or three die every week, and although many of these are well known not only to me but to experienced general practitioners, distinguished physicians and surgeons, and recognized dietetic experts no personal letter has, so far as I know, been sent to the Parliamentary Secretary to the Minister of Food. Yet I feel sure that all these doctors are just as much concerned about the welfare of their patients as Dr Foxell. I must conclude therefore, that they found other means of helping and encouraging their patients whom they could not hope to cure instead of demanding a vital foodstuff which at the best could do no more as in Dr Foxell's case than prolong an unhappy existence and which the medical advisers to the Ministry of Food considered could be better used for the prevention or cure of diseases or the alleviation of definite symptoms such as difficulty in swallowing.

Many tuberculosis officers did indeed think it right to assist as far as possible in the representations which were made by various bodies to the Ministry of Food in order to obtain as far a deal as possible for the tuberculous. It now seems that we might have armed ourselves with the appeal of a dying patient and faced the Ministry of Food with the dilemma either of acceding to our requests for extra rations, thereby providing

an example which would have nullified their carefully thought-out plans for a fair distribution to the population as a whole or of refusing them, thereby exposing themselves to the criticism that they had made a decision about a patient in defiance of our requests without making a personal examination. Of course this criticism might have appeared even more childish when applied to a large number than it does when applied to Dr Foxell's apparently (though not in fact) isolated case. Moreover this method of forcing the claims of one section of the community might itself have been exposed to the criticism that it was grossly unfair and unreasonable. Perhaps we were deterred by these considerations, and perhaps Dr Foxell would have been deterred from writing his letter if he had looked at the problem as a whole instead of concentrating on one patient. No doubt his devotion to his patient was worthy of praise, but would he have received so much support and flamboyant publicity in your columns if you had not been hard up for a piece of hot propaganda to hurl at the National Health Act? And will this object be achieved by attacking the Ministry of Food, which many people think is an example of co-operation between doctors and laymen in running a necessary national scheme in a very successful manner? During six years of their control there has been little if any complaint of the flouting of medical opinion, and if this is a foretaste of control under the National Health Act it may be asserted that this Act could scarcely have a better recommendation—I am, etc.,

London NW 3

G A BACK

The Plebiscite

SIR—The result of the plebiscite was as much surprising as it was disquieting. It is not so much that so many voted 'Yes' but that so many abstained from voting. Doctors have never been known to pull together, and it is this lack of unity and want of *esprit de corps* that shows up our weakness and leaves us open to attack from any quarter that is intended.

True, the wording of the plebiscite was somewhat ambiguous. I believe that many voted 'Yes' because of the fear of victimization. The wording would have been more appropriate if it had been in two parts: (a) Do you want to negotiate for a complete State Service? (b) Do you want to negotiate for an amended or extended Service? I am perfectly sure that 90% would answer 'No' to (a), for they are very few who want to be the complete Civil Servant. I have no doubt that 100% would answer 'Yes' to (b) for it is time that the Government did something to improve the Service for which we have been so long clamouring and which would be acceptable to the profession. The difference between (a) and (b) is that one is 'tyranny' and the other 'freedom'.

We are a noble profession and not an industry, and it is high time that Mr Bevan was told once and for all that doctors will not tolerate nationalization in any form. If the doctors would stick together and be of one mind, then they, and not Mr Bevan, would do the table thumping—I am, etc.

Nottingham

S J BRENNAN

SIR—The result of the plebiscite has shown that 56% of those who voted were against negotiations. This is only a little more than half and when one considers that 20% of all doctors abstained from voting it is clear that the B.M.A. Council has no justification in refusing to negotiate as it has less than half the profession behind it. Furthermore many of the 'No' votes were given as a result of the recent threatened 'strike' of Insurance Acts practitioners which was successful in winning concessions from the Minister. Many thought that a little more defiance would be good for him and that he would then relent and presumably start all over again. Many more voted 'No' as a political gesture against the Labour Government which they as Tories of the old school dislike so much.

This negative attitude is clearly unreasonable and cannot possibly do the profession any good. Mr Bevan will go ahead to establish the Service in the knowledge that he has about half the profession willing to help. Yet we in the helpful half are debarred by the Council's decision from negotiating with

the Minister on the regulations, and giving him the technical advice which will make the Service a success. Now that the Act is law it is our duty as citizens to make it work, and to clothe the framework, making an administrative skeleton into a humane National Medical Service working solely for the good of the patients and the prevention of disease, and thinking less as time goes by of a mercenary profit motive—I am, etc.

Wolsingham

WILLIAM D GRAY

SIR—Stung by the results of the medical plebiscite Mr Bevan now writes to say that if the B.M.A. will not talk with him he will consult with other interests to assist him to set up the administrative machinery for the new Health Act. Why not say this before? It is exactly what the Negotiating Committee have been asking him to do. And primarily we want to ask him to consider whether some compromise cannot be found over the basic salary. Does this mean that in the long run we are to become Civil Servants, or that the basic salary is to be a means of tiding over the period while ex-Service doctors and young medical men settle down into practice under the new Service? If the latter, will it not be possible to agree for a term of years and then free the profession to such independence as we have had under the N.H.I. Act without restricting regulations which can never meet all the changes and chances of disease in human nature?—I am, etc.

Broadstairs

H M RAVEN

B.M.A. Policy

SIR—In a letter in the *Lancet* on Dec 28, Mr T. B. Layton makes so many confused statements that it is impossible to deal with them in the space of a short letter. However, it is very necessary to correct the loose statements suggesting that the leaders of the B.M.A. have "herded the will" of the profession and influenced the plebiscite vote.

The official B.M.A. communications received by me have always been restrained and non-directive, as have been the editorial articles appearing in the *Journal* on the subject of the recent Act. The correspondence published in the *Journal* accurately reflects the opinions freely expressed at the well-attended Divisional meetings of practitioners. Those of us who know Mr Layton may sit back and smile tolerantly, but statements such as appear in his letter are apt to produce a false impression in the mind of the general public that the results of the plebiscite do not really reflect medical opinion.

A recent article in the *Times* contained the word 'emotional' as applied to B.M.A. policy. If the adjective is accurate it must be applied to the general body of practitioners, and I would point out that situations which conflict heavily with any individual's conviction of right and wrong will usually produce emotional response—I am, etc.,

Stratford

E C TILL

SIR—Dr H. B. O. Cardew in his letter (Jan 4 p. 29) makes several dramatic and unjustified accusations, closing with the sentence "I accuse the British Medical Association Council of adopting a narrow sectional viewpoint at a time of immense social change when it should be leading the profession towards the creation of a great health service." With these words Dr Cardew not only accuses himself but convicts himself of adopting a sectional viewpoint, for he suggests that the Council should lead the profession in a direction which the majority consider to be against the public interest—I am, etc.,

London NW 1

R. HALE-WHITE

The Decision

Lipetz's problem (Jan 4 pp. 29 and 30) let us recall as only doctors of 60 and over can what happened in December 1912 re service under the Lloyd George Act of 1911. Then after a rousing campaign round about 95% of practitioners pledged themselves to refuse service. In the last week of the year word went round in every district that a doctor or two had "gone on the Panel" (Some of these had

NOW AVAILABLE—

'PALUDRINE'

The New Antimalarial

The production of 'Paludrine' in increasing quantities now enables demands for this important drug to be fulfilled without delay

Extensive clinical investigations have established that 'Paludrine' is a highly efficient antimalarial with definite advantages over mepacrine and quinine

- A single dose of 'Paludrine' (one or two tablets) controls the clinical symptoms of all forms of malaria and terminates the attack
- 'Paludrine' is a true causal prophylactic in malignant tertian malaria and a partial causal prophylactic in benign tertian malaria
- It produces radical cures in malignant tertian malaria, and a dose of one tablet once a week is sufficient to control the relapses of benign tertian malaria indefinitely
- 'Paludrine' is a colourless drug and in normal dosage does not produce unpleasant symptoms of any kind

'Paludrine' tablets of 0.1 gramme strength are issued in packings of 30, 100 and 1,000

Vitamin Therapy *its uses and limitations*

B COMPLEX:

RESIDUAL DEFICIENCIES

Recent clinical reports show that it is frequently impossible to clear up all symptoms of specific vitamin deficiency diseases by the use of a single indicated vitamin preparation, but that residual symptoms are left which require the administration of one or more other factors of the vitamin B-complex. Such considerations are found to apply in beri-beri, pellagra, the "burning feet" syndrome and the dermatological conditions associated with ariboflavinosis. Bearing this in mind two points should be noticed: 1—the inclusion in Befortiss B-complex of pyridoxin (vitamin B₆) and 2—the presence of adequate amounts of all four factors.

BEFORTISS

B-complex capsules

Each capsule contains		
Aneurin hydrochloride 10 mg	Riboflavin	10 mg,
Nicotinamide 150 mg	Pyridoxin	0.5 mg,

Elastoplast Technique was evolved with 'Elastoplast' Bandages and Dressings. The successful results described in medical and surgical publications were achieved with 'Elastoplast' Bandages and Dressings.

The combination of the particular adhesive spread with the remarkable stretch and regain properties of the woven fabric, together provide the precise degree of compression and grip shown by clinical use to be essential to the successful practice of the technique.

These properties, peculiar to 'Elastoplast', have produced a bandage used for many years with outstanding success by the Medical Profession throughout the world.

Elastoplast

BANDAGES AND PLASTERS

Made in England by T J Smith & Nephew Ltd, Hull

REMINDER: Smith & Nephew Plaster of Paris Bandages now carry the universal Trade Mark 'GYPSONA'

(not signed the pledge others had) What happened? The est met hastily in groups, considered the situation and—sent n their names With n 10 days over 95% were in the service In short, 19 out of 20 would not serve, 19 out of 20 did The est, the diehards had to choose between retirement, specialism, and starvation I write this not cynically but as relevant history

What then? It is abundantly plain to me that we must negotiate and both for the public's and our own sakes, help to make the best possible Service The Divisions should back negotiation and the S R M Jan 28, either reject Dr Cockshut's motion and call upon the Negotiating Committee to carry on, or amend this motion so that a new (? minority) committee can be appointed, to serve not only the Yes voters but also the Noes if the latter course is adopted I hope to see Mr H S Souttar in its Chair carrying on the great work he did in presiding over the Medical Planning Commission, the foundation on which the new Act is built—I am, etc.,

W ARNOTT

Totland Bay Isle of Wight

National Health Service

SIR—There is one weakness in our armour with regard to our attitude towards the Government Health Scheme which may easily prove our undoing At the plebiscite everybody was of course entitled to vote as he thought fit But if the minority should be allowed to accept service under the present Bill the Minister of Health may easily be in a position to organize a skeleton service and there can be very little doubt that other members of the profession will gradually filter into the Service In such a contingency we would be broken and come under the dictatorship of fifth-rate officials

I suggest therefore, that we should endeavour to persuade the minority not to accept service I suggest that we should insist that we ourselves provide the medical service, and that the Government merely act as representative of the public to see that we carry out our undertakings I am quite sure that such a service would be acceptable to the majority of our profession—I am, etc.,

Liverpool

I HARRIS

SIR—I think it possible that the most important question in connexion with the National Health Service Act is being overlooked in the discussion of the plebiscite results This question surely is whether the Act will provide a better medical service for the nation If an affirmative answer can be given there must be reasons of great moment to justify the leaders of the British Medical Association advising the profession not to participate in the shaping of the Act

Certain obvious benefits will be conferred on the public by the Act most important perhaps will be the ending of the financial burden of illness and the delays in seeking treatment which this sometimes entails The public know also that under the Act they will be able to obtain free specialist advice and treatment when necessary The hospitals will be able to provide a better service as they will not be limited in their work by lack of funds and the general practitioner service will eventually be more fairly spread throughout the country This should reduce the inconveniences suffered by patients especially in the poorer districts which result from overcrowded surgeries and rushed and harassed doctors Furthermore under the Act (Clause XVI) the Minister will be empowered to encourage and finance medical research

The Health Service Act should not be viewed as an isolated piece of legislation but as an integral part of a great legislative plan for achieving social security The people of this country, by their welcome of the Beveridge report and by returning a government to power pledged to introduce social security, have expressed their hopes and wishes in these matters

If the leaders of the B M A should now advise a course calculated to frustrate a vital part of the plan for social security they will I fear incur the anger and contempt of the majority of the people It is to be earnestly hoped that they will not adopt this course and oppose a measure which, in spite of all its defects is so plainly designed to be a great and lasting benefit to the nation—I am, etc

JOHN PEMBERTON

A Bad Press

SIR—It is strange that, although individually the doctor is generally liked and respected, collectively as a member of the medical profession he is everybody's Aunt Sally' The recent reaction to our recoil from a bad Act is only one more illustration Two related factors are, I think, involved First, everyone hates and is afraid of certain diseases Evil spirits cannot be blamed in these enlightened" days, but the old habit of substitution is employed, and upon a scapegoat is unloaded a heavy weight of displeasure What more natural than to choose for this purpose the doctor so closely associated with the trouble I have heard it said "that everyone is afraid of the doctor" meaning, I suppose, that collectively he is used to canalize much dread, and fear easily becomes dislike Secondly, pretended omniscience is always hated Yet from the days of the Delphic Oracle to our own times, say in the case of a medicine man practising in the Australian bush, infallibility has always been courted Once again the doctor willy nilly has been cast for this role Who cannot remember his *obiter dicta* to an assembly of anxiously waiting relations? Perhaps the *Times* leader writer to whom you refer has permitted these or similar considerations to influence him—I am, etc.,

London SW 1

E GALLOP

The Negotiators

SIR—As one of the small majority of general practitioners who voted against negotiation by the present Negotiating Committee with the Minister on the new Health Act I should like to express my point of view, which has not so far been quite the same as other expressed views but may not be unique I voted No as an expression of no confidence in the present Committee to represent the present generation of doctors The point of view of the Committee as I heard it expressed by Dr Dain in this area last summer shocked me as being reactionary muddled and fogging the issue by too many points some relevant others not relevant It is not for doctors to express their opinion at this time about the State control of hospitals I would stand for ever against the deprivation to doctors of the right of appeal to the Courts and against the Minister's power to repress the Annual Report of the Central Health Council But I am not going to stand upon the question of salary or buying and selling of practices provided my living is secured and my professional integrity assured Further I wish my future discussed by men and women of young and middle age, and not by those, however able, over 65—I am, etc

Ruthin

ENID A HUGHES

The Surgeons and the Act

SIR—At the special meeting of Fellows of the Royal College of Surgeons of England on Nov 29 (*Journal* Dec 7, p 869) the President said that 'The Council has to answer in a corporate capacity the question whether it desires the Negotiating Committee to enter into discussion on the framing of such regulations Might one ask why? The President then goes on to say that As a corporate body the Council has answered 'Yes' and later when adversely criticized by a majority of the Fellows present, complains how difficult and distressing the position of leaders of the profession might be If the 'leaders of the profession' make decisions of high policy without first consulting their electors their position will become increasingly difficult and distressing

The President ended by saying that he himself held the view strongly that at this stage it was their duty to negotiate I wonder if he still holds this view after the Willesden episode rightly described in the *Journal* as outrageous If a medical officer matron and nurses can be dismissed for refusing to join a trade union before the coming of a National Health Service anything can happen when and if it does come The Willesden councillors have had to save their face, but they have not changed their heart

If the word 'outrageous' seems a trifle strong to the Socialists think what would happen when a Conservative Government was in power if any municipal employee who joined a trade union was dismissed

The red light is showing, municipalities up and down the country are taking away freedom of action from

employees For some extraordinary reason employees earning over £700 in Rotherham are exempt Let us beware, our turn will come If 23 000 of us stand firm for freedom and stick to our principles, we shall prevail And let us hope that the 'leaders of the profession' will not jump into the big jobs, as they have in other walks of life, until the matter has been thrashed out to the very bottom to the satisfaction of the majority of the profession—I am, etc,

Rotherham

ERIC COLDREY

SIR,—Many practitioners have expressed concern over the ill-informed attitude of the Councils of the Royal Colleges towards the National Health Service Act Mr G Housden's timely letter, 'Surgeons Up in Arms' (Dec 21, p 960), is to be welcomed I have even heard the College Councils referred to in some quarters as the 'Bevan Boys' It is to be hoped that these bodies will realize that they have a serious responsibility towards the public and the profession, and that in medico political matters they will co operate with the better informed BMA

The freemen of the profession are to be congratulated on the wisdom of their plebiscite decision At last the BMA has its mandate, and if the medical profession possesses the courage of the Willesden nurses the Association will not be lacking in strong support United, we have the power to defeat the unhealthy designs of any political party The problem confronting us is not primarily one of health It is a purely political matter, the real motive being to control the doctors and thereby their certificates in order to secure the financial aspects of the social security scheme This should be made clear to the public

I believe I am not alone in the fear of a general moving towards National Socialism in Britain If this is a true conception of recent events we have a clear duty towards the community as well as the profession to resist State control with all the power at our command We must win the first round of the battle against National Socialism Then, and not until then, we can proceed to consider a scheme designed to improve the health of the nation—I am, etc,

Guildford

J O M REES

Medical Students and the Act

SIR—I am a medical student It is not for me to condemn men of wisdom and experience in the profession I have chosen to follow, but medicine is my future and therefore I consider myself justified to take part in the somewhat vitriolic discussion on the National Health Service Act Perhaps the term medical student may lead many to associate me with 'adolescence' May they not be deceived My wife is a general practitioner and I am ex-Indian Army and a liberal

What I abhor in the approach of many doctors is their obvious disregard in their written criticisms for the social problems which exist in our over-industrialized community No alternatives or secondary schemes have been offered to replace the National Health Service Act as it stands Amendments cannot be classified as an alternative scheme Recent correspondence has been metalled with 'for the honour of our profession' "we utterly disapprove," and many similar utterances of indignation The Government has been criticized, but no evidence exists in the public mind of a pitched battle on the grounds that the medical profession have put forward a more palatable scheme and that the Government turned it down

The Act has become law But will any doctor deny the need for a health service for the poor?—not necessarily a scheme governed by politics, such as the National Health Service Act Why not a health service on the scale of an increased panel system to include the wives and families of their menfolk on the panel, or that all persons whose income is below a certain figure be included in the panel? The prestige of the BMA would have risen greatly in the public mind if they had fought the Government with counter-proposals for a National Health Service Instead the public are fogged and remain silent

The public have risen as one body and with one mind over the nationalization of transport Why did they not rise up and oppose the National Health Service Act? I suggest it was because they did not, and still do not, understand the full implications of the Act The poorer classes need such benefits

badly, and the remainder of the public are prepared to accept the Act on those grounds There was no large scale publicity plan to show the public that there were other ways of serving the basic purpose of the Act without the destruction of the profession as it is known to-day Here I must class the medical student He does not know which side to support How can he without any guidance from the BMA? He tends to support the national scheme and looks on the present unconstructive attitude of the instituted members of the profession as the collective protestations of a hen being disturbed on her nest I repeat, the BMA has never enlisted public support against the Act Who, or what body is in a position to stand against the dictatorial impositions of the present Government? A handful of nurses broke up their methods Surely such a powerful organization as the BMA, standing on untouchable ground, can find a way to institute a health service of its own? No doctor can be compelled to enter the State Service, and if all the writers in these columns of past months stand by their maxims of "for the honour of our profession, they will put their heart and soul into any such venture which might give the country one concrete instance that our Labour Government is not an idol to be worshipped under compulsion

Lastly, it would be unwise to forget the small army of mature medical students now studying at universities throughout the country Their support would be valuable to any counter scheme started by the BMA, but that support can never be obtained if they are continuously kept in the dark with regard to their own future—I am, etc,

London S W 6

DAVID McQUEEN

* * Mr McQueen's suggestion in the third paragraph has been BMA policy for many years—ED, B M J

Reiter's Disease

SIR—From the many references to Reiter's disease that have recently appeared in the *Journal* it seems that several misconceptions exist on the subject Much of the confusion would appear to be due to the fact that the disease bears Reiter's name, since the case described by him does not seem to me to have been a true example of "Reiter's disease" as we now know it In his case (described in 1916) the illness was ushered in with severe abdominal pain, diarrhoea and blood stained stools, followed eight days later by a purulent urethral discharge with bilateral conjunctivitis and, on the ninth day, an acute polyarthritides This appears to me to have been a clear case of dysenteric polyarthritides

It is interesting to note that Feissinger and Leroy, in a study of an epidemic of dysentery on the Somme in 1916, noted before Reiter the same clinical syndrome (syndrome conjunctivo urethro synovial) in four of their cases They also described a case of amoebic dysentery with conjunctivitis and arthritis Dysenteric arthritis, often monarticular (it was so in all the cases reported by Bonnin and Kay), is a not infrequent sequel in some epidemics of bacillary dysentery, and although it may occur during the acute stage of the disease it is met with more often during convalescence

Reiter's disease, as it is generally recognized to day, is characterized by a clinical syndrome consisting of non gonococcal urethritis bilateral conjunctivitis, arthritis (usually polyarticular) and occasionally balanitis and keratoderma blennorrhagica This was, in fact, recognized many years before Reiter published his case and was described by Launois in 1899 Launois's case was of venereal origin, and in my experience this is always so with this disease It consists of a variety of non gonococcal urethritis with blood borne complications, it runs a protracted course and sometimes recurs after long periods of remission Urethritis is usually of the Waelchli type and characterized by a longish incubation period and multiple subjective and objective signs and symptoms In some of my cases however, there was a profuse purulent abacterial urethral discharge with pain and frequency of micturition Cases have been reported with upper urinary tract lesions, and a case at present under my care which was admitted with haematuria, non-gonococcal urethritis bilateral conjunctivitis, and polyarthritides, shows dilatation of renal pelvis In my series conjunctivitis was noted between 2 and 16 days after the appearance of the urethral discharge, and arthritis (always polyarticular) 1 to 6 days later In one case however, arthralgic pains in several joints were observed 2 days before the onset of conjunctivitis and definite articular involvement did not occur until 4 days later Fifty per cent of my cases subsequently developed keratoderma blennorrhagica I have also had several cases of primary non gonococcal urethritis with metastatic complications in which the syndrome was incomplete

The venereal syndrome is also seen in association with a gonococcal urethritis, but in these cases there is often a primary mixed infection of both gonorrhoea and non gonococcal urethritis and evidence is accumulating that the latter is the real cause of the condition. Reiter isolated a spirochaete in the blood of his case, but in this respect all subsequent workers have failed. Macfie in 1917 reported a case of primary spirochaetal urethritis with arthralgic pains and iritis; the condition reacted favourably to galyl and mercury. Your annotator refers to this case—wrongly, in my opinion—as being one of Reiter's disease.

Reiter's syndrome has also been noted in cases suffering from staphylococcal septicaemia by Biland in 1905 and Junghanns in 1918. Biland's case a man aged 21 with osteomyelitis of the right acromion process, non gonococcal urethritis bursitis, and subcutaneous abscesses (all due to *S. aph. aureus*) had the primary focus in the acromion process although the author did discuss the possibility of primary urethral involvement. Junghanns himself considered that his case in a boy aged 16 with non gonococcal urethritis, conjunctivitis and polyarthritis was due to a generalized septic infection arising from a boil on the upper lip. Many cases of arthropathic psoriasis have been described wrongly as cases of Reiter's disease but confusion here rests with the differential diagnosis of the skin lesions: the rupoid eruptions may be indistinguishable from the soft parakeratotic patches which are an occasional manifestation of keriodermia blennorrhagica. The syndrome in arthropathic psoriasis is never complete and usually consists of arthritis and skin lesions only.

I described in 1944 the presence of inclusions (initial and elementary bodies) in the urethral discharge, conjunctival secretion and skin lesions and these findings have been confirmed in the investigation of further cases. Dienes and Smith in 1942 cultured pleuropneumonia like organisms from the urethral discharge of a man suffering from arthritis, and Henderson Begg has recently isolated this organism from the urethral discharge of one of my cases of Reiter's disease.

Fever therapy is the treatment of choice. In my experience penicillin and the sulphonamides have no beneficial effects.

In conclusion I would like to put forward the suggestion that a distinct differentiation should be made between cases of venereal origin and dysenteric origin. I advocate that the term Reiter's disease or better still dysenteric arthritis, be applied only to the latter and that the former—those of venereal origin—be described as non gonococcal polyarthritis or the non gonococcal syndrome. Much confusion would, I am convinced, be avoided by such a distinction—I am, etc.

Antibiotics and Canine Distemper

SIR—Some of my colleagues may perhaps be interested in the use of penicillin for the bronchial complication of distemper in their pets. Recently my wire-haired terrier developed distemper complicated with bronchitis of a severe type. The dog was seen by two veterinary surgeons who confirmed the diagnosis and considered his chances of survival were practically nil. Sulphonamides had been given in adequate dosage for about one week the temperature remaining high—105° F (40.6 C)—and with little if any apparent benefit. I suggested intramuscular penicillin 200 000 units of the sodium salt; this was injected and within twelve hours the temperature had fallen to 102° F (38.9 C) and after a second dose of 200 000 units given twenty four hours later it fell to normal—100° F (37.8 C)—and remained there. The terrier had an uneventful recovery and is now (three weeks later) quite well much to its owner's delight.

It is said that penicillin has little or no effect in virus diseases of which this is one so it may have been the secondary organisms in the bronchial complications that were sensitive. I understand that the recent epidemic of distemper in dogs is of Canadian or U.S.A. origin and of a virulent nature and many other dogs have been attacked with fatal results. The effect of penicillin in this one case was so dramatic that the veterinary surgeon in question decided to use it in other dogs' attacks—with equally gratifying results. Though one or two swallows

do not make a summer it may be that, as in this case, penicillin may have a place and many valuable pets or prize dogs may be saved by its use—I am, etc.,

S A MONTGOMERY

Immunization against Whooping-cough

SIR—Dr H Sugarc (Dec 7, 1946, p 876) will be interested to know that the "field trials" of whooping-cough vaccine (Nov 9, p 699) are now being extended to Leeds, where a new British alum-precipitated vaccine is to be used. Despite the good results claimed in the U.S.A. previous trials in this country have not been very promising, and until a definite assessment of the value of pertussis vaccines is made in Britain it is considered undesirable to associate them in the minds of parents with a procedure of proved efficacy such as diphtheria immunization. When a vaccine of proved value is available the next step will certainly be to test it in combination with diphtheria toxoid as a combined antigen would be of great advantage to the child and to all concerned with immunization schemes—We are, etc.

Hospital Regions

We print below a letter sent by the King Edward's Hospital Fund for London to the Ministry of Health.

SIR—We are grateful for the opportunity afforded by your letter of Nov 15 to comment on the areas proposed for the regions in the London area.

I am to say that the proposals as they affect the London area are fully in accord with the view which this Fund has from time to time expressed. It is essential that the hospital services of London and the Home Counties should be taken together, and that the arrangements should be such as to secure to the full the advantages expected to accrue from the extension of the university influence upon the standards of hospital work. At the same time we appreciate that the area is as a whole too large to be operated as a single region and we would agree that the division of the area into four regions offers the best practical alternative open to the Minister. In saying this we would not wish to prejudice the question of the advisability of some reconstruction of the boundaries of the regions on the lines now being suggested by the Voluntary Hospitals Committee for London.

The experience of the Fund shows that it is especially in the populous periphery of the Metropolitan area that the need for further development is most apparent. This development must be completely integrated with the hospital services of the central area and we are strongly of opinion that the advantages of such a plan as that now proposed will in the long run far outweigh the possible conveniences of any alternative plan such as might be framed to coincide with the present boundaries of the County of London. This alternative could only tend to perpetuate the defects of the present arrangements (see enclosed paragraphs 11 and 12 of the Statement of Principles submitted to the Ministry in 1944).

11 In the case of London, the regional arrangements must cover part or the whole of the area of the Home Counties however this area may be ultimately defined. It may be that special arrangements will be called for as regards the regional machinery.

12 Although the size of the area of the authorities remains to be determined the White Paper contains a hint that it will be necessary to have regard to administrative convenience, and implies that the area of the London County Council will constitute a single authority. The experience of the King's Fund in the Metropolitan Police District proves unmistakably that such an arrangement would only perpetuate one of the primary sources of the maldistribution of hospital facilities in the metropolitan area. In so far as there is a lack of adequate hospital services in the London area it is to be found on the periphery of London where new populations have sprung up within recent decades—where it has proved difficult for voluntary provision to keep pace with the growth of population and where the local authority has equally failed to meet the situation. If ever there was a case for co-ordinated planning it is over this wide area that transcends the County boundaries.

—I am, etc

Obituary

SIR RICHARD CRUISE, GCVO FRCS

Sir Richard, Robert Cruise, who died on Dec 24 at St Mary's Hospital, London, after a brief illness, had been Surgeon Oculist to Queen Mary since 1936 and before then Surgeon Oculist to King George V.

Born at Purneah, India, son of Francis Cruise he was educated at Harrow and St Mary's Hospital, qualifying in 1900 and taking the FRCS three years later after he had worked as house-surgeon at the Bristol Eye Hospital and had spent some time in Paris clinics. He continued his ophthalmic studies at Moorfields Hospital, where he became chief assistant, and he was also for some time senior clinical ophthalmic assistant at St Mary's.

(Bussano Ltd)

During the war of 1914-18 he served with a temporary commission in the R A M C in France and at the 3rd London General Hospital at Wandsworth, and he did valuable work as ophthalmic surgeon to King Edward VII Hospital for Officers. His principal appointment in later years was that of surgeon to the Royal Westminster Eye Hospital, and he was also consultant oculist to the Harrow Cottage Hospital.

Richard Cruise was a most accomplished operator, shown perhaps at his best in cataract

cases. He retained his operative skill and was in harness up to the time of his death. While serving in France he had invented a chain visor for attachment to the rim of the soldier's steel helmet and he described this device in a paper on 'Protection of Eyes in Warfare by Adoption of the Author's Visor' which appeared in the *Transactions of the Ophthalmological Society* in 1917. He also published in that periodical an account of his operation for the restoration of contracted and disorganized eye sockets (1919), and of hinge-flap sclerotomy for glaucoma (1940). Early in his career he wrote a monograph entitled *Clinical Refraction*. He was made a CVO in 1917, a KCVO in 1922 and a GCVO in 1936.

An open air man of wiry physique and polished appearance he hunted regularly for many years, was an expert shot, and a good golfer. Few if any medical men can have ridden so successfully in point-to-point races over a long period. He owned the famous steeplechaser War Gratuity, so named because he bought it with his war service gratuity. That horse won many races with him in the saddle and died while he was riding it in a steeplechase fifteen years ago.

Sir Richard Cruise was popular with his colleagues and always ready to help or advise. He joined the British Medical Association in 1906 but did not hold office at Annual Meetings and took no active part in professional politics. In later life he spent many happy days at his country house Shipton at Winslow in Buckinghamshire, while continuing to practise in Wimpole Street.

SIR HARRY WATERS MRCS DPH

Sir Harry Waters who died recently at Stroud in Gloucestershire, at the age of 78 had a distinguished career as a public health administrator in India and was chief medical officer to the East Indian Railway from 1917 until his retirement in 1923.

Harry George Waters son of Alfred Waters was born at Rathmullen in Co Donegal on April 19 1868 and was educated in England at the Royal Naval School New Cross, and at St Thomas's Hospital. He qualified as MRCS, LRCP in 1892 and afterwards obtained the DTM&H and the Cambridge DPH. Having held house appointments at the Hull Royal Infirmary he went out to India to join the medical service of the EIR. Besides his ordinary duties he

was appointed an honorary magistrate and plague officer at Tundla, in the United Provinces, in 1907, and six years later held the corresponding posts at Jamalpore, in Bengal. He was responsible for the establishment of laboratories at Tundla and at Allahabad and throughout the war of 1914-18 held the rank of Lieut-Colonel in the Indian Defence Force, and was later gazetted as honorary Colonel. Before his return from India he examined in hygiene at Calcutta University for two years and was a member of the Bengal Sanitary Board and president of the Conference of Chief Medical Officers of Railways. In his leisure time he was a keen rifle shot.

During the past twenty-three years Sir Harry Waters took a prominent part in local affairs at Stroud and continued his active interest in the teaching of first aid. He had started the St John Ambulance classes on the East Indian Railway in 1897, was a Knight of the Order of St John of Jerusalem, and received the Volunteer Decoration. At Stroud he had been honorary pathologist to the General Hospital. During the recent war he was medical officer to the local company of the Home Guard with the rank of captain in the 7th Battalion of the Gloucestershire H.G. He was also a JP and at one time chairman of the Stroud Urban District Council. He received his knighthood in 1924 in recognition of long service to public health in India. He married in 1900 Dr Winifred Pierce a medical graduate of Edinburgh University and they had two sons, one of whom has already had a distinguished career in the Indian Medical Service.

Medico-Legal

A RADIOGRAPHER ELECTROCUTED

It is some time since a death from electric shock by an x ray apparatus was reported. The last case of the kind occurred in Wimbledon in the early thirties. A nurse imprudently put a hand too near the cathode when a patient was being screened and she and the doctor were killed. As a result every firm promptly introduced shock-proof apparatus, and most medical men probably assumed that this danger had been eliminated. A radiographer, however, was recently killed by shock at Derby.

According to a newspaper report¹ Dr H G Grace said at an inquest that after he had screened a patient he had told the radiographer Mr V I Marshall that it would be necessary to make certain adjustments to the equipment. Marshall, he said stood at the control table making adjustments and watching results. He then moved away to inspect the meters close at hand. He gave a small jump backwards apparently to make a further adjustment. There was a brilliant white flame and he slumped to the floor. He was at once treated for shock but did not recover. The doctor said in answer to the coroner that certain parts of the apparatus were not shock-proof. Completely shock-proof apparatus was very difficult to acquire.

A representative of the manufacturers said that the machine had been standard equipment when installed in 1936. It would be possible to get an electric shock from a "tremendous number of points on the apparatus, which would transform up to 100 000 volts. The coroner said the corporation had failed in its duty to its employees and everyone else by having a machine like this unless efforts had been made to get a shock proof apparatus. He referred to evidence that other insufficiently shielded machines were in use in the town and hoped that speedy steps would be taken at public hospitals and private institutions to ensure that no danger existed. He expressly excepted Dr Grace from his criticisms.

¹Derby Evening Telegraph Dec 14 1946

Dr George Jessel, of Eccles Lanes who died on June 23, left £30 840. Dr W H Dobie, who died on March 3, left £18 000. Dr Charles James Rovston, of Bournemouth who died on Oct 6, aged 46 years left £20 310. Dr John Barbour Stewart, of Kirkintilloch, Dumbartonshire, who died on Aug 15 last left personal estate in England and Scotland valued at £16 837.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS
OF GLASGOW

A Lecture entitled "Surgery of the Thyroid Gland" will be delivered by Mr. Geoffrey L. Keeney FRCS in the Hall of the Royal Faculty of Physicians and Surgeons 2-2, S. Vincent Street, Glasgow on Wednesday Jan. 15 at 4 p.m.

A meeting of the whole medical profession in the Birmingham area will be held at the Nuffield Hall, Queen Elizabeth Hospital Birmingham on Sunday Jan 12, at 6.30 p.m., to discuss the resolution of the Council of the B.M.A. regarding the N.H.I. capitation fee and the action to be taken by the Negotiating Committee and to instruct representatives to the Special Representative Meeting on Jan 28.

A joint meeting of the Food Group of the Society of Chemical Industry and the Liverpool Section of the Society will be held at the University of Liverpool on Tuesday Jan 14, at 6.30 p.m., when Mr P. N. Williams will present a paper on "Synthetic Fats".

The annual general meeting of the Harveian Society of London will be held at 26 Portland Place, London, W, on Wednesday Jan 15 at 8.15 p.m. when the president Brig H. L. Glyn Hughes will deliver his presidential address on "Normandy to the Baltic from a Medical Angle".

A meeting of the Royal Sanitary Institute will be held at 90 Buckingham Palace Road, S.W. on Wednesday, Jan 15, at 2.30 p.m. when a discussion on 'Health Centres' will be opened by Prof. R. H. Parry.

The following radiological meetings will be held in London next week: Thursday, Jan 16 8 p.m., British Institute of Radiology, 32, Welbeck Street W, discussion on "Cardiac Radiology" to be opened by Dr T Holmes Sellers Dr D Evan Bedford and Dr J Duncan White; Friday, Jan 17, at 2.30 p.m., Diagnosis Section of Faculty of Radiologists at Royal College of Surgeons of England, Lincoln's Inn Fields, W.C., paper by Mr J J Mason Brown on "Arterial Injuries with Reference to Arteriography in the Diagnosis"; Friday Jan 17 at 8 p.m., Section of Radiology of Royal Society of Medicine, 1, Wimpole Street, W, papers by Dr S Nowell "Tomography," and Dr A Elkeles, "Disseminated Ossified Nodules in the Lungs associated with Mitral Stenosis."

A meeting of the Eugenics Society will be held at the Royal Society's Rooms, Burlington House, Piccadilly, W., on Tuesday Jan 21 at 5.30 p.m. when Sir Alexander Carr-Saunders, Sir Cyril Burt and Dr J H Fraser Roberts will present a symposium on 'The Relation of Intelligence to Fertility'. All interested in the subject are invited to attend.

The King has appointed Dr Edgar Cochrane to be an Official Member of the Legislative Council of the Colony of Aden

Mr J J Robertson, Labour M.P. for Berwick and Haddington has been appointed to the General Medical Council in succession to Lord Hacking. He is one of the five members of the Council nominated by the Crown. Mr Robertson, a 48-year-old Shetlander has had a varied career—*retail fruit merchant in Edinburgh, middle weight champion of the Navy in 1918, at the Ministry of Supply in the recent war, and M.P. since the general election*

The British Postgraduate Medical Federation is shortly to be recognized by Royal Charter as a school of London University with Sir Francis Fraser as Director. The Maudsley Hospital Medical School will become an Institute within the Federation. For the academic year 1946-7 the University has granted the Federation £147 000.

The Royal Medical Foundation of Epsom College invites applications for a Chalice annuity, present value £32 per annum, which is to be awarded to a medical practitioner who, on account of age has been compelled to retire from professional work. There is no limitation as to age. Forms of application can be obtained from the secretary's office, Epsom College, Surrey.

The Hospital for Tropical Diseases which was closed during the war has now been reopened at 23 Devonshire Street, London W1 (Tel. Welbeck 8371), and is open to all patients suffering from tropical diseases. There is an out patient department for which appointments should be made by telephone or by letter.

A team of medical and public health workers from Ceylon are visiting this country for six months under a scheme arranged between the National Association for the Prevention of Tuberculosis and the Ceylon Government to study tuberculosis control treatment and rehabilitation, as well as sanatorium methods and mass

The Ministry of Health announce the ending of the arrangement whereby relatives of Merchant Navy men dangerously ill in hospital could apply to the police for a railway warrant.

D- Annecke, Chief Malaria Officer for South Africa, recently announced further extensions of Operation Arthur the anti-malarial campaign that has been waged in Eastern Transvaal for the last three seasons. He said that, given the man-power, the whole of the Transvaal and the Union could be cleared of malaria.

Prof O N Holsti, professor of medicine in the University of Helsinki and President of the Finnish College of Physicians, is on a visit, arranged by the British Council, to this country to study British medical developments and, in particular rheumatology, endocrinology, metabolism, and the teaching of medicine. Dr Cruz Coke a former Minister of Health in Chile, is also on a visit to Britain, arranged by the British Council, to renew contacts with British medical authorities.

The Royal London Ophthalmic Hospital, the Royal Westminster Ophthalmic Hospital, and the Central London Ophthalmic Hospital have united under an Act of Amalgamation, and are now called the Moorfields, Westminster, and Central Eye Hospital. The hospital will provide clinical material and facilities for postgraduate teaching and research. 341 beds are available.

The National Collection of Pathological Specimens of War Injuries of the Medical Research Council (Curator, Dr Joan M Ross) is now housed at the Examination Hall, 8, Queen Square, London, W C 1 (Tel Terminus 3270).

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* an increase was recorded in the incidence of measles 812 while there was a decline in cases of scarlet fever 191, diphtheria 87 and whooping cough 78.

Large increases in the notifications of measles were reported from several counties, the largest rises were Warwickshire 195, Northumberland 161, Worcestershire 151, Durham 149, Devonshire 108 and Middlesex 103. The greatest contrasts to the general trend were decreases in Kent 99 and Essex 95.

Small decreases in the local incidence of scarlet fever were recorded throughout the country, the largest return was that of Yorkshire West Riding 38. No marked fluctuations in the local trends of whooping-cough were reported. The largest variations in the incidence of diphtheria were decreases in Lancashire 28 and Yorkshire West Riding 14, with a rise in Durham 14. The only large centre of infection of dysentery was Lancashire, Preston R D 11, only scattered cases were recorded in other areas.

In *Scotland* there were decreases in the notifications of measles 78, whooping cough 42, and diphtheria 18 and rises in the incidence of acute primary pneumonia 30 and dysentery 15. The rise in cases of dysentery affected the eastern area, and Edinburgh reported an increase of 6 cases. In Glasgow the cases of acute primary pneumonia rose from 163 to 185.

In *Northern Ireland* another large increase, 130, was recorded in the measles epidemic in Belfast C B.

Quarterly Returns for Eire

The birth rate during the September quarter was 22.9 per 1,000, which was the same as the rate for the third quarter of 1945. Infant mortality was 54 per 1,000 registered births, this was 4 below the rate of the September quarter of 1945 which was the lowest rate since 1942. Maternal mortality was 1.6 per 1,000 registered births compared with 2.6 for the corresponding quarter of the previous year. The general death rate was 11.5, and was 0.4 below the rate for the preceding third quarter. Deaths from pulmonary tuberculosis were 561, 184 were attributed to other forms of tuberculosis. These figures were 93 and 20, respectively, below the totals for the third quarter of 1945.

Deaths in the United States

During 1945 the total of 1,401,719 deaths in the United States was fewer than in either of the two preceding war years. The principal cause of death was heart disease which accounted for 30.3% of the total, deaths from cancer accounted for 12.7%. The relaxation of rigid wartime driving restrictions coincided with a rise in deaths due to motor-vehicle accidents from 24,282 to 28,076. Deaths from infectious diseases declined and new low records were set up for deaths from pneumonia and influenza, these causes accounted for 68,386 deaths, 16.4% below the total for 1944 and 8.2% below the previous record low level of 1942. Tuberculosis caused 52,916 deaths which were fewer than in any previous year. Deaths in the first ten months of 1946 were estimated to be 1,162,000—as compared with 1,144,373 in the same period of 1945.

Week Ending December 28

The notifications of infectious diseases in England and Wales during the week included scarlet fever 943, whooping cough 1,149, diphtheria 210, measles 7,038, acute pneumonia 760, cerebrospinal fever 38, dysentery 55, paratyphoid 6, typhoid 3.

No 51

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec 21.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. *Figures of Births and Deaths and of Deaths recorded under each infectious disease are for:* (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1946					1945 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	29	4	21	—	—	43	4	13	—	2

Deaths (0-1 year) Infant mortality rate (per 1,000 live births)	5.39	7.3	9.6	3.0	—	4.54	6.2	5.2	4.9	1.2
Deaths (excluding still births) Annual death rate (per 1,000 persons living)	5,682	945	721	171	—	6,088	979	665	234	141
Live births Annual rate per 1,000 persons living	9,158	1403	1137	25	—	6,890	956	841	332	239
Stillbirths Rate per 1,000 total births (including stillborn)	2.69	2.9	3.5	—	—	2.27	1.4	3.1	—	—

* Measles and whooping-cough are not notifiable in Scotland and the return are therefore an approximation only.

† Includes primary form for England and Wales (London (administrative county) and Northern Ireland).

‡ Includes puerperal fever for England and Wales and Eire. It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct 26, Nov 2, 9, 16, 23, 30, Dec 7, 14, and 21. No returns this week for Eire (notifications).

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Convalescent Serum in Measles

Q—A child 18-months old in a town full of measles—what precautions would you advise? Would you give particulars about the use of convalescent serum?

A—Convalescent measles serum may be used either to give complete protection or to render the attack a mild one in a child who has been intimately exposed to infection. Children of six months to two years of age are highly susceptible both to attack and to the risk of secondary complications such as otitis media and bronchitis or bronchopneumonia. Therefore a child in this age group should if possible be completely protected. This is done by giving, within five or six days of exposure, 5 ml. of pooled convalescent measles serum recently harvested or if not recently obtained dried to preserve the antibody. (If the exposure is a family one the date on which the rash appears in a patient is regarded as the fourth day of exposure of a contact.) Protection lasts for a few weeks only and then the child becomes susceptible again.

A danger attached to the use of human serum is that the serum may contain the icterogenic agent of homologous serum jaundice but in an extensive use of convalescent measles serum the writer has not encountered this condition in young children. Supplies of convalescent measles serum are very limited, and as an alternative a child may be given double the dose of a pooled adult serum, which may not however, give complete protection. For an exposed healthy child over 2 years of age adult serum or a small dose of convalescent serum should be used in order to let the child have a mild infection with resulting immunity to future attack. Serum should not be given unless the child is known to be intimately exposed, and serum is of no value after the onset of clinical symptoms. Inquiry as to supplies of convalescent measles serum or adult pooled serum should be made at the local public health laboratory or from the public health department.

Penicillin Chewing-gum

Q—Is penicillin chewing gum of any value? If so how is it prepared?

A—According to Catherine F. McIntosh and P. W. Perryman (*Pharmaceutical Journal* Dec 7, 1946 p. 345) penicillin chewing gum is best prepared by warming commercial chewing gum to about 40°C and rubbing it in a mortar with 200,000 units of dry calcium penicillin. After thorough admixture the mass is rolled and then cut into 20 pieces each thus containing 10,000 units.

The penicillin content of saliva remained high for seven hours while such gum was chewed. Gum made with sodium penicillin was active for only four hours and a tablet of the same amount of calcium penicillin only with no gum produced an effect for only two hours. It is recommended that each piece of calcium penicillin chewing-gum be chewed for four hours, three pieces daily. The method is said to give good results in Vincent's gingivitis and it has been applied to the treatment of throat infections. This method of administration may well prove with further experience to be both more agreeable and more effective than the sucking of the penicillin tablets now available.

Horripilation and Perniosis

Q—What is the treatment of horripilation or 'goose-flesh'? The patient is a young teacher and the condition persists throughout the year. The upper arms and thighs are chiefly affected and the underlying skin has a dusky red appearance.

A—The brief description suggests that this patient has pernio that is a poor peripheral circulation and an exaggeration of the follicles is a usual accompaniment. It is however not very satisfactory to make a diagnosis from

such scanty information. If my suggestion is correct, then measures directed towards the poor circulation may be helpful: warm clothing, warm environment at home and work, physiotherapy by way of massage exercises, and ultraviolet light, and possibly quite small doses of phenobarbitone and thyroid. Vitamin K seems to exercise a beneficial effect in some cases of pernio. The follicular reaction may also be in part a local nutritional failure consequent upon the poor circulation. In such cases vitamins A and D by mouth are helpful, and a simple emollient ointment or glycerin lotion may be used on the skin.

Ephedrine and Desensitization

Q—If an allergic patient is undergoing non-specific desensitization and ephedrine is given to relieve the headaches which follow injections does this interfere with the desensitization process?

A—The giving of ephedrine or adrenaline to relieve symptoms produced by either specific or non-specific desensitization is an accepted practice and does not interfere with the desensitization process.

Trichomonas Vaginalis and Salpingitis

Q—Despite the fact that the uterine secretions are normally alkaline and so presumably limit the spread of a trichomonas infection upwards does infestation of the uterus occur, and if so might it lead to a salpingitis and to pelvic peritonitis? I have a woman patient who had *Trichomonas vaginalis* in the vagina following laparotomy and salpingectomy after the sudden development of pelvic peritonitis. The thin pus leaking from the funicular end of the Fallopian tube failed to show anything on culture.

A—All the evidence so far available shows that the *Trichomonas vaginalis* does not ascend to the uterus or Fallopian tubes. This point was investigated by E. Allen and S. Butler (*Amer. J. Obstet. Gynaec.*, 1946, 51, 387), who state: 'We have been unable to demonstrate any ascension of the trichomonads above the external os of the cervix. We have examined material from the surgical specimens removed from 28 patients with active trichomoniasis. The material was obtained within a few minutes after operation. It was examined in saline suspension, cultured (technique described by Trussel and Plass) and stained (Leishman's stain described by Liston). The material was taken from the uterine canal tubes, ovarian cysts, pelvic and ovarian abscesses, and amniotic fluid. No trichomonads could be demonstrated.' These authors go on to give a warning against operating in the active stage of a trichomonas infestation since convalescence tends to be stormy. They also suggest that the bacteria found concomitantly with a trichomonas infestation may infect the uterus or tubes especially in the premenstrual phase.

It seems therefore that in the case under consideration some bacterial infection must have been responsible for the salpingitis and pelvic peritonitis. Several points must be borne in mind. A flare-up of a pre-existing chronic or subacute salpingitis is especially likely to occur in the premenstrual phase. Gonorrhoea and trichomonas vaginitis may co-exist. Cultures taken at laparotomy for acute salpingitis are often sterile even when an organism such as the gonococcus can be demonstrated in the cervix and urethra. It seems that in this case some other cause for the salpingitis than trichomonas infestation should be looked for.

Risks of Cellulose Spraying

Q—What dangers are there in the cellulose spraying of motor cars if a proper mask is used?

A—The risk to health in this work is from the volatile components of the cellulose paint and not from the solids. These volatile substances vary widely but from the health aspect probably the most important are benzol, methanol, and butanol. A mask, to be effective, must be designed to prevent the inhalation of vapours rather than dust; hence the usual type of mask with dust-filtering media is useless for this work. Except perhaps for occasional work of very short duration adequate protection is in fact obtainable only when the spraying

operation is effectively under the influence of mechanical exhaust ventilation. In considering the health hazards the fire risks of cellulose spraying should not be forgotten.

Approach to Persecution Mania

Q—*What is the best method of getting a lady with a persecution mania to a psychiatrist? What is the correct attitude to take should one be sympathetic or otherwise?*

A—It is not advisable to use subterfuge in getting the patient to see a psychiatrist. If nothing will induce her to consult a competent specialist, she must be permitted to go her own way. However, the wisest method of approach does not seem to have been used so far. The deluded patient, who is not conscious of feeling ill in any way, commonly resents the suggestion that he or she is 'mentally affected,' or that his or her false beliefs are the result of 'imagination' (which, of course they are not in any case). It is not possible to discuss their symptoms with deluded people unless one accepts some common ground, which includes the reality of their experiences. A sympathetic attitude is certainly best. The suggestion might be made that the feelings in question are not infrequently the result of an interference with the orderly functioning of the nervous system arising from some physical cause for which specialist advice would be helpful. If this is rejected, reasonable excuses for calling in psychiatric aid may usually be found within the logic of the delusional beliefs—e.g., as a suitable preliminary to reporting the persecution to the police.

Alcohol Test for Milk

Q—*What is the alcohol test for the keeping quality of milk? How is it performed?*

A—The alcohol test is carried out by adding 1 ml. of 68% ethyl alcohol to 1 ml. of the milk and inverting the tube once. If precipitation of casein (i.e., discrete particles however small) is observed in the thin layer of liquid adhering to the walls of the tube, the test is regarded as positive. The alcohol is prepared by diluting industrial methylated spirit with distilled water to approximately 68%, neutralizing any free acid and confirming the final concentration by determining the specific gravity, which should be 0.895 at 15.5°C. Freshly drawn milk should be pre-incubated at 20°C for eighteen hours before testing.

Ulcers of the Mouth

Q—*A healthy woman patient has had for a year painful buccal ulcers which take several days to reach their peak and several more days to heal following the most trifling trauma. Have you any suggestions as to aetiology and treatment?*

A—Painful ulcers of the mucous membrane of the mouth appearing in spasmodic attacks which die down and then recur are not infrequent, particularly in women. Bacteriologically they are often associated with a mixed streptococcal and pneumococcal flora, and this type often reacts well to local penicillin. Others show only mixed oral types of organisms, and these do not appear to react so well. The fact that very slight trauma appears to initiate the ulcers suggests that the mucous membrane is not in a particularly healthy state. It might therefore, be advisable to give a course of vitamin therapy, massage of the mucous membrane with glycerin and tannic acid is also at times helpful. Ulcers of this kind are sometimes associated with infected tonsils, which appear to act as a focus of infection.

Treatment of Priapism

Q—*I have seen four cases of priapism. Two were treated by incision, two by bromides and ice-bags. Recovery was slow. Is there any other treatment?*

A—Priapism may be reflex in origin or due to some local cause, such as injury, inflammation, or new growth. Treatment will therefore vary with the aetiology. Persistent priapism due to thrombosis will generally require operation in the way of incision of the swollen corpora cavernosa. As an alternative to this aspiration may be tried using a needle of large calibre. It must be confessed that the treatment of this condition is on the whole unsatisfactory and that convalescence is inevitably slow.

Letters and Notes

Village Longevity

Dr J. PIRIE (Harbury) writes: Looking over my death certificate book I find the ages of my last entries are 89, 77, 75, 89, 82, 90, 74, 84, 74, 77, 87, 78, 40 (pulmonary tuberculosis), 32 (pulmonary tuberculosis), 87, 73 (carcinoma). My practice is a country one in a well known hunting district with only a few industries—mainly cement works—and in many cases very primitive sanitation and a sad lack of decent houses for the working classes.

Record of Service

Dr CHARLES HERBERT HALL of Watford has been secretary of the West Herts and Watford Medical Society since Sept. 18, 1896. This remarkable record of fifty years service to a medical society which will celebrate its centenary in 1948 is, at the least, unusual. It will be interesting to know if any reader can equal or improve on it. Not so unusual is the fact that Dr. Hall has a son who is in practice, and a grandson who has just ceased to be a Naval Medical Officer.

Apparatus for Trichlorethylene in Midwifery

Dr C. F. SCURR (Barnet) writes: Referring to Dr. John W. Scholey's letter (Nov. 9, p. 722) I have used trichlorethylene in the Oxford vaporizer for the production of analgesia in midwifery with excellent results. The machine is used cold, the lever is set for a reading of from 4 to 7 and the mother herself holds the mask on her face. On occasion, by increasing the concentration of trichlorethylene administered full anaesthesia has been produced for the insertion of sutures into the perineum.

Swiss Holidays for Children of Doctors Killed in the War

In connexion with the Swiss Red Cross "Save the Children" scheme a generous offer has been made by the Swiss medical profession to accommodate in Switzerland for three months the children of British doctors killed during the war. The names of children between the ages of 4 and 13 are being recorded at B.M.A. House, and any practitioner who has personal knowledge of a family entitled to take advantage of this offer is requested to communicate with the Secretary of the British Medical Association, giving all relevant details. The scheme already covers the children of French and Belgian doctors who were killed or totally incapacitated in the war.

Re-inoculation with T.A.B.

Lieut. Col. H. G. G. ROBERTSON, R.A.M.C., writes: With reference to the question and answer (Nov. 23, p. 803) regarding T.A.B. inoculation the standard Army practice may be of interest. Primary inoculation consists of one dose of 0.25 ml. followed by a second of 0.5 ml. 10–14 days later. This is regarded as being effective for 12 months. Re-inoculation consists of one dose of 0.25 ml. If more than three years has elapsed since the last inoculation the patient is considered to have lost his immunity and primary inoculation is then necessary again. In the case of tetanus toxoid the doses are two of 10 ml. each at intervals of 6 weeks, and the same rule applies regarding re-inoculation. In both cases immunization is normally carried out only when an individual is proceeding overseas.

Milk Priority

Dr G. A. POWELL-TUCK (Birmingham) writes: May I suggest that all persons who receive the old age pension be permitted to have half a pint (285 ml.) of milk per day. This would at least allow them a warm drink before retiring to bed.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: ARTICULATE, WESTCENT LONDON. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone, unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publisher, Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proof. Authors overseas should indicate on MSS. if reprints are required as proof are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: ARTICULATE, WESTCENT LONDON.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: MEDISCEA, WESTCENT LONDON.

ENDOCRINES IN GYNAECOLOGY*

BY

ALECK BOURNE MB, FRCS, FRCOG

There is no doubt that the discovery of the sex hormones has conferred an enormous boon on the drug manufacturers, but we cannot be so confident of the benefit to the suffering patient. After the early experiments which demonstrated their striking effects on the structure and function of the genital system of laboratory animals we had high hopes that they would exert comparable effects when used for the treatment of pelvic disorders in women. But with some well-defined exceptions we have been grievously disappointed. The reasons why this should be are not far to seek. This branch of medicine was initiated in 1917 by the observation by Stockard and Papanicolaou that injection of the liquor of the Graafian follicle produced oestral changes in the vaginal mucosa. From this fundamental discovery has been built up our knowledge of the secretions of oestrogen and progesterone, of their effect on the development of the genital tract and on the cyclic changes of the endometrium later of the gonadotrophins of the pituitary and their relation to the ovary. The greater part of this work during thirty years has been done by experimental work on small animals and monkeys.

Difficulties in Clinical Use

Herein lies the first reason for clinical disappointment. It was hoped and expected that the precise result obtained by injecting this or that hormone into rats and rabbits would be similarly obtained with the human patient. But the mechanism of the endocrine system is infinitely complex, not only in the individual species but also in its variations in different species even closely allied. It was soon realized that deductions made from observation of one animal could not safely be made for another species, and still less where the other species was human. Moreover the experimental work has been done on either normal animals or those which have suffered a severe and totally mutilating operation such as ablation of the pituitary gland. Our patients are not normal animals nor have they been subjected to severe surgical mutilation except, rarely, by removal of both ovaries. Clinical experience has shown that deductions made from the reactions of animals to hormone treatment cannot be applied to parallel treatment of the pelvic disturbances of women.

A further difficulty is adequate dosage for the human subject. Whereas the synthetic oestrogens can now be given in any amount it is probable that the substitute pituitary hormones (chorionic gonadotrophin and mare's serum hormone) can be given only in doses totally inadequate for the proportional weight of a woman. As the pituitary hormones—the gonadotrophins—are the prime

movers of ovarian function, it is impossible to influence ovarian function, for example folliculation, except by the appropriate gonadotrophin in sufficient dosage. So far it has been impossible to synthesize these extremely complex bodies and I am told there is also little prospect of success in the future. Fortunately, hormones can be extracted from the urine of pregnant women and the serum of the pregnant mare, which can be obtained in larger amount for clinical purposes than from the pituitary itself, but the available doses of even these pituitary-like hormones are probably far too small to exert an appreciable clinical effect.

The rhythmical secretion of the sex hormones of the pituitary and ovary introduces a further complication in therapy. It is necessary to know the details of the rhythm of normal secretion if we wish with some hope of success, either to apply reinforcement to subnormal activity or to counter the action of an oversecretion. During the first fortnight of the menstrual cycle the pituitary produces its follicle-stimulating hormone and the ovary oestrogen, while during the second two weeks the pituitary secretes its luteinizing hormone and the ovary progesterone with less oestrogen. For any given complaint therefore, we should know not only whether there is an excess or deficit of the particular hormones responsible but also the time in the cycle when the therapeutic hormone should be given. In other words, unless the correct hormone is given at the right time in the menstrual cycle there cannot be any improvement, indeed, the patient may be worse.

But after we have noted the difficulties dependent upon the differences of the species, inadequate dosage and timing, perhaps the greatest of all is the complexity which arises in the human subject by reason of the profound effect of the highly organized emotional system on the hormonal function of the pituitary. We see this in our gynaecological practice almost every day. Amenorrhoea and certain cases of menstrual excess so often follow emotional storms of one kind or another that it is impossible to deny the association. It is probable, too, that toxic goitre, even sterility and many other states, similarly depend on interference with pituitary function by anxiety, fear and anger while *per contra*, we may perhaps attribute a smooth function—or euphonia, as the Greeks called it—to contentment, exaltation and translation out of ourselves. We may be correct in assuming the basic effect of oestrogen in man from the experimental evidence gained from the small animals but the result of any given treatment may be totally different from what we should expect from purely physiological considerations, because of the incalculable effect of emotional interference with the functions of the pituitary body. A good example is the treatment of the

* Annual Address to the Oxford Medical Society given on Nov. 29 1946

menopause by stilboestrol. Sometimes the patient finds complete relief from her flushes and sweats, but those women who are emotional or 'temperamental,' especially if they have had unhappy years, will find little improvement. But at this period the basic physiology is the same in most if not all women. The ovaries atrophy, probably owing to the cessation of the secretion of pituitary gonadotrophins. Menstruation ceases, and usually there are various subjective symptoms. The latter, however, are extraordinarily variable both in degree and in responsiveness to hormone treatment. Their intensity depends less on the actual hormonal imbalance than on the influence of temperament and the level of happiness and content during previous years of married life.

Endocrine Receptors

There is still one more unknown factor which may be important in endocrine therapy. I have seldom seen it mentioned, and never considered, in therapeutics. I refer to what I call endocrine receptors. When, for example, a large dose of oestrogen is injected into an adult female certain definite changes are found in certain organs, and those organs only. The endometrium proliferates, the uterus of the immature animal grows, and the vaginal mucosa cornifies. But there are no other demonstrable changes (except possibly indirect) in most other tissues of the body. It is doubtful if after millions of units the alimentary mucosa, for example, would show the slightest change at all. It is necessary, therefore, to postulate the existence of receptor substances in the vaginal mucosa, the endometrium, and a few other tissues, which are able to grasp the oestrogenic molecule and, perhaps by chemical union, enable it to perform its specific function. I visualize the characteristic changes in the reproductive organs as being the result of a dual and co-ordinated action of two substances—the activator and the receptor. In our therapeutics we consider only the activator—the hormone—but it may be that failure of the expected result to follow is due to absence of its vaginal or uterine receptor, without which it is powerless to exert its specific function. How far subsequent research may reveal and identify visceral receptors we do not know, but until we know something about them our endocrine therapy must remain largely empirical. It is possible that many pathological disturbances, such as amenorrhoea, are due to failure not of the appropriate hormonal secretion but of their necessary receptors in the ovary and uterus.

I have recently investigated a case which illustrates the existence and absence of these receptor substances. Briefly, a woman of 36 had had amenorrhoea for five years due to no apparent cause. Radiography and the sound show the uterus to be atrophied, and the curette could not remove more than the smallest fragments of endometrium for the microscope. The sections reveal no evidence whatever of oestrogenic action, and as the uterus has atrophied both in structure and in function we must assume that it has not received the oestrogenic stimulus. But in this woman the curious thing is that the vaginal mucous membrane manifests quite strongly that oestrogen is circulating in the blood stream. For example, the acid reaction gives a reading of the normal pH 4.5 by the universal indicator, the smear of its secretion shows an enormous number of Doederlein's acid-forming bacilli, and the histology of the epithelium reveals a very large amount of glycogen, similar to that of normal women during the child-bearing period. These features of the vagina are proof that oestrogen is present in the body in normal amounts, and yet the uterus is unable to receive it and so exhibit the ordinary histology and development characteristic of the presence of the circulating oestrogen. My

inference is that, while the vagina is able to react the uterus lacks something by which it also can react.

If this inference is true, should we not review some of our endocrine therapeutic failures from a different angle? From the evidence of animal experiments we are entitled to expect certain results from the sex hormones, especially when we work with oestrogen and progesterone, which can be injected in reasonable doses. But often in clinical medicine we are disappointed. Is this failure possibly due to the fact that we are using the wrong substance, and if we could replace a missing receptor—as in my illustrative case—should we not immediately see the expected reaction? It is obvious that we need more research on the tissues or soil on which the sex hormones normally act. The earlier years of the science of bacteriology were conspicuous for the same omission. The organisms were explored in the minutest detail, but the tissue cell and fluid resistance was largely neglected. Now we know that in the phenomena of infection the organism is only part, perhaps a small part, of the whole process of infective disease. Indeed, in this branch of medicine it is now recognized that the reaction of the tissues to the microbic assault is at least equal in importance to the biology of the microbes themselves. When, therefore, we consider all the difficulties which beset endocrine therapy—the correct hormone, its dosage and timing in the menstrual cycle, the effect of the emotional life, and the ignorance and neglect of receptors—it is surprising not that we find many failures but that we have any success at all.

Treatment by endocrine hormones has, however, definite fields of usefulness, and there is a wide fringe of partial or occasional success which will vary according to the faith of the patient in her doctor and to his confidence in the value of his injection. Endocrinology offers perhaps the widest scope in the whole of medicine for treatment by confidence. Where symptoms rather than signs are the object of treatment—such as the menopausal syndrome as opposed to the undeveloped uterus—we find the chief success. On the other hand, in the certain suppression of lactation there is a specific organic result of the action of oestrogen.

Hormones and Their Functions

Let us consider, first, what hormones we have at our disposal. By far the most important is one or other of the oestrogens. The natural oestrogens commonly used are oestradiol benzoate, oestrone, and oestriol, sold under different trade names by different makers. The synthetic oestrogens are stilboestrol, bexioestrol, and dienioestrol, the two latter being one-sixth and one-tenth as potent, weight for weight, as stilboestrol. They have the advantage over the natural oestrogens in that they are soluble in water and can be given by mouth. Oestrogen therapy is convenient, precise, and sufficient in dosage. The second ovarian hormone is progesterone, the product of the corpus luteum. In the process of its metabolism it is "denatured" and finally excreted in the urine as the inert water-soluble pregnanediol. Unfortunately for therapeutics, progesterone must be extracted from the corpus luteum, which means that the available dosage will be small and expensive. The synthetic product, sold as ethisterone, can be given by mouth, but it is much less potent, and is also scarce and expensive. It is indeed unfortunate that we have no adequate treatment by the corpus luteum, for it is one of the most important of all the sex hormones from the point of view of therapeutics. Lack of progesterone in adequate dosage is responsible for most of the failures in treating common conditions like amenorrhoea and dysmenorrhoea. The two hormones oestrogen and progesterone work so closely together—as for example, in forming the progesta-

onal endometrium and the decidua—that, with two or three exceptions, it seems almost hopeless to produce any therapeutic results by giving oestrogen alone, as is so often done.

The anterior pituitary secretes two well-recognized sex hormones. One is the follicle-stimulating hormone formerly called prolan A, which stimulates the maturation of the Graafian follicle and production of the ovum, the other is a hormone which initiates the corpus luteum after rupture of the follicle. It was formerly known as prolan B, but is now commonly known as the luteinizing hormone. If we were dependent upon the pituitary alone as the source of these hormones there would be no practical use for them in clinical medicine, as the gland is so small and the yield insignificant. But it so happens that the serum of the pregnant mare during the middle of her pregnancy contains large quantities of the follicle-stimulating hormone, which can be extracted and put up in fair dosage. It is sold by various makers as "serogan," "antostab," "gestyl," and "gonadyl" in doses of from 200 to 3,000 units. The second gonadotrophin, the luteinizing hormone, can be obtained from the urine of pregnant women. It is not precisely the same substance as that secreted by the pituitary, but is very similar in its effect. It is produced by the chorionic cells of the placenta, whence its name—chorionic gonadotrophin.

Before we dwell upon the practical value of the sex hormones in therapeutics let us pause to consider their chief functions. The proximal group is the pituitary secretions. It is believed that during the first two weeks of the menstrual cycle the follicle-stimulating hormone is produced. Under its influence a single immature Graafian follicle ripens, secretes oestrogen, and dehisces the ovum on the 13th day though this date is by no means constant. At the moment of rupture of the follicle the secretion of this hormone ceases by reason of a reciprocal inhibitory action of the follicular oestrogen on the secretion of the pituitary follicle-stimulating hormone. During the second fortnight is secreted the luteinizing hormone, whose function is to convert the follicle and maintain the corpus luteum and its hormone, progesterone. In its turn the secretion of the luteinizing hormone ceases, the corpus luteum degenerates during the next thirty-six hours, and menstruation begins. So far as we know, the pituitary gonadotrophins have no other function than these actions upon the ovarian follicles and corpus luteum. It is improbable that the story is as simple as the alternating action of two separate hormones. It is more likely that other ovariotropic hormones exist which, for example, control the rupture of the follicle and together form a complex group of gonadotrophins. Of the "terminal" ovarian hormones, oestrogen is the best known. It is essentially the oestrus-producing hormone, but other changes it induces are the growth of the genital tract at puberty, the conversion of the endometrium into its proliferative phase after menstruation, and the cornification of the vaginal epithelium. Its action, preceding that of progesterone, is necessary for the appearance of menstruation.

Progesterone has been employed to a smaller extent than oestrogen because the difficulty of synthesis makes it impossible to provide large enough doses. Its chief function is to produce the secretory or progestational phase of the endometrium, in readiness to receive the fertilized ovum. Immediately the ovum is fertilized the endometrial change is carried a step further to form decidua. The integrity of the decidua is dependent upon the secretion of progesterone until about the fifth month, for if during this time the corpus luteum is removed or fails in its secretion—as shown by a low excretion of pregnanediol in the urine—the

decidua breaks down and haemorrhage follows as the uterus aborts. It was formerly thought that progesterone was a kind of uterine sedative, but it is now known that the uterus is irritated through the influence of posterior pituitary extract to a greater extent during the luteal phase of the cycle than during the oestrogen or post-menstrual phase. A practical example is that usually progesterone given for dysmenorrhoea before the period makes the pain worse. It is incorrect to think of the ovarian hormones as having wholly separate and independent functions. They certainly induce different changes in the endometrium, but no normal function, whether it be menstruation, conception, pregnancy, or, probably, labour, can take place unless they work in harmony. The earlier view that oestrogen and progesterone were "antagonistic," though correct in a limited sense, has impeded the progress of successful endocrine therapy by leading us to neglect the idea of their synergism, and to think only of their antagonism.

Therapeutic Value of Sex Hormones

Having sketched the great difficulties of practical clinical application of the sex hormones and touched on their functions, what now of their therapeutic value? The main clinical problems, such as amenorrhoea, menorrhagia, dysmenorrhoea, sterility, and the menopause, seem to be due to deficiency or excess and disordered rhythm of their production. But of this we are not sure, for the disturbance may be due to disproportion of secretion of one hormone relative to another. It always amazes me to hear some physicians talk of the hormonal defects of one or other of their patients. They say with confidence and precision which hormone is lacking or excessive and just how the trouble can be compensated by giving a grain of this or a milligram of that.

If we divide the sex-organ disabilities into those which are functional or subjective and those which are objective or organic, and examine the effects of treatment by hormones of each group, we shall be better able to appraise their true value. It is not easy to draw a sharp line between the so-called functional and organic conditions, for there are always likely to be some structural changes, even if at the beginning they are only microscopic. But in general we mean by functional conditions those which are not associated with organic conditions discoverable by ordinary clinical, x-ray, or other examination. Of the organic states often treated by hormones the chief are pelvic hypoplasia or underdevelopment as a cause of amenorrhoea or sterility, lactation when it is necessary to suppress it, atrophy of the vulvo-vagina (kraurosis), leucoplakia, and metropathia. If we are honest with ourselves we must admit that the only certain success in treatment is the suppression of lactation by the oestrogens. If we give 15 mg of stilboestrol daily for three or four days we can assume that engorgement will disappear and lactation will cease.

In cases of pain in older women due to atrophy of the vulva (kraurosis), or senile vaginitis due to a pyogenic infection, there is frequently either complete cure or much relief following oestrogen therapy, within three or four weeks. Similarly, some cases of chronic vulvo-vaginal infection in children will also clear up after the use of vaginal pessaries of 1,000 units of oestrogen.

But if the pain of kraurosis is relieved by oestrogen it is certain that leucoplakia, which is an epidermal hypertrophy and always a new growth in its late stages, not only is not improved but is probably increased. No form of anaerobic infection of the vagina, as by the common enterococcal streptococcus—sometimes associated with the symbiotic *Trichomonas*—is touched by oestrogen therapy, because these organisms can live comfortably in the acid

medium of the vagina, which is increased by oestrogen. One of the commonest and most serious states is pelvic hypoplasia. Here we have failure of complete development of the uterus and often of the vagina and vulva. There may be full development of the secondary sex characters, or the woman may show some degree of virilism. Usually she is apparently a normal woman except that puberty was late, menstruation is imperfect, perhaps absent, sometimes but by no means always painful, and if she is married she may complain of vaginal dyspareunia and sterility. It is difficult to diagnose uterine hypoplasia by clinical examination; it can be proved only by comparative x-ray shadow or the uterine sound. I am convinced that no amount of combined oestrogen and progesterone treatment can add half a centimetre to the uterine stature. In some of these cases amenorrhoea can be apparently cured, so long as the oestrogens are given, by producing the so-called withdrawal haemorrhage, but primary amenorrhoea can never be cured and that form of amenorrhoea which is secondary to early uterine atrophy—not necessarily a true menopause—also can never be cured by the sex hormones. Where, therefore, amenorrhoea is "organic" it can seldom if ever be replaced by a normal regular and permanent menstruation.

Sterility offers a different problem. It is certain that the underdeveloped uterus presents no difficulty to embedding of the fertilized ovum, even if the progestational phase of the endometrium is imperfect, because we know that the ovum can embed itself in the tube or even the ovary. The failure of conception is probably due to the associated failure of ovulation where the uterus is underdeveloped. The small uterus is the chief clinical evidence of smallness of function, including ovulation. The problem of sterility in these cases is therefore how to treat function by producing ovulation, the condition of underdevelopment is less important. In the follicle stimulating hormone of the pregnant mare's serum we hoped that we might have a means of inducing ovulation. I have used it many times in doses of 1,000 units in carefully selected cases during the post-menstrual ten days, but in only one woman has conception occurred after treatment during three months. Pregnancy progressed to term, and at last, after eight years of trying to conceive, she has got her baby. In no other case can I honestly say that the serum gonadotrophin has possibly worked. Many schemes of hormone therapy have been used for sterility of all kinds, and here and there successes have been claimed, but we must remember that the arm of coincidence is long, especially when dealing with such a condition as sterility.

Another organic condition is metropathia (it should be named oophoropathia), causing profuse and irregular haemorrhage. It is probably true that the irregularity of haemorrhage in cycle, duration, and amount is due to disordered rhythm of production of the follicle and corpus luteum. During the periods of bleeding no corpus luteum exists in either ovary, and the endometrium shows an intense oestrogenic stimulus. One ovary contains unruptured follicles the fluid of which is much more highly charged with oestrogen than the normal Graafian follicle. The obvious endocrine treatment is therefore to give an anti-oestrogen—progesterone or testosterone. Scowen (quoted by Bishop) has shown that very large doses of progesterone (20 mg. on alternate days) will effect improvement lasting for many months after ceasing the injections. A more certain remedy is testosterone propionate, but again the doses must be large (20 mg. twice weekly). This male hormone acts by overcoming the female oestrogen and ultimately inducing genital atrophy and virilism. It must therefore be used with great caution. Whatever

improvement short of atrophy may be induced is temporary in moderate or advanced cases, and most of these patients must submit to x-rays or hysterectomy according to their age. Mild cases of excessive loss with irregularity can often be controlled for a while with progesterone, but the treatment is expensive and unreliable. Among the truly functional conditions there are the menorrhagia of puberty and the subjective symptoms of the menopause. Certain cases of spasmodic dysmenorrhoea form a large group, and many attempts have been made to treat repeated threatened abortion and inertia in labour, of which many cases are functional. As a means of inducing premature labour oestrogen is quite unreliable even when given in such doses as half a million units. The disorders which can be grouped as sexual frigidity or "functional" dyspareunia are entirely unresponsive to oestrogen. The haemorrhage of puberty, like that of metropathia, is probably due to failure to establish ovulation, with the consequent deficient secretion of progesterone. The child is under the influence of an uncontrolled action of oestrogen which produces oestral haemorrhages and not true menstruation. When investigating these cases many years ago Dr. Charles Wilson (now Lord Moran) and I found evidence that these patients were in a state of hypothyroidism as measured by the basal metabolic rate. If this is generally true it may be that thyroid deficiency is no more than a side issue of general endocrine incoordination. Some enlargement of the thyroid is often seen at the age of puberty, and in such cases I always give small doses of thyroid extract or iodine. The logical treatment, as in the case of metropathia, is to give large doses of progesterone, but in my experience this is seldom the right course. Most of these children are being pushed for school examinations. They are overworked, tired, thin, pale, and sometimes anxious about the school certificate. The best treatment is to rest them by removing them from school for a term and keeping them in bed during the days of worst bleeding. Really serious cases are very rare, and nearly all of these patients soon become normal.

In dysmenorrhoea we have the biggest problem of all, as is manifest by the multiplicity of methods of endocrine treatment. Of the many theories advanced to explain severe first-day pain, my own view is that it is caused by intense uterine contraction with coincident spasm of the internal os—as we often see in painful first-stage labour—producing obstruction to the outflow and ischaemia of the muscle. It is indeed uterine colic. The uterus seems to lack polarity, or co-ordination between fundal contraction and cervical relaxation. The worst case of dysmenorrhoea I ever saw was in a woman, previously without any monthly pain, for whom I amputated the cervix. Severe pain immediately followed the operation, and on investigation, after the second painful period, under anaesthesia I had the greatest difficulty in passing a filiform bougie. When, however, I had finally dilated the stenosed os by a tent, the pain entirely disappeared. In the less severe cases almost any treatment, especially if given by injection, may be successful for a few months. The rational therapy would be some measure which relieved the irritability of the uterine muscle and at the same time relaxed the spasm of the internal os. In practice we find that progesterone before the period is not only useless but may actually increase the pain, just as it often expedites threatened abortion by stimulating the uterine response to posterior pituitary extract. It is also useless to treat dysmenorrhoea on the supposition that the uterus is underdeveloped, for Jeffcoate has shown that pain is caused by the normal uterus equally with the small uterus. Oestrogens, given during the post-menstrual week in rather large doses—5 mg. daily—may relieve pain by inducing an anovular cycle, but there is nothing

approaching certainty either by this or any other form of hormone treatment

The subjective symptoms—flushing, sweating, and many nervous symptoms—of the natural menopause are nearly always relieved or even abolished by oestrogen. It is necessary to impress on the patient that stilboestrol or dienoestrol must be taken only intermittently—say for two weeks, followed by one week without treatment—and that it should not be continued indefinitely. Many cases of post-menopausal bleeding which we see to-day are found in women who have been taking stilboestrol literally for years. They suffer from an intensely oestrogenic proliferative endometrium which oozes blood by reason of its congestion. But while oestrogens are invaluable at the natural menopause they are disappointing when given after radium, x rays, or double oophorectomy. Implantation of oestrogen pellets is similarly useless, though this method has striking success for a year or so when used for the natural menopause. Implantation of oestrone is, however, a risky procedure as it may cause repeated irregular haemorrhages and it may be necessary to remove the pellet.

Lastly we come to repeated abortion. During early pregnancy, excretion of pregnanediol—the final inert product of progesterone—increases greatly, up to 50 or 60 mg daily. Where the excretion is markedly low it is stated that abortion is certain. It is well known, too, that removal of the corpus luteum before the 20th week will be immediately followed by abortion. It would therefore appear that for those patients who abort by reason of defective secretion by the corpus luteum progesterone given from the earliest weeks until the 20th week would provide an effective substitution therapy. The estimation of pregnanediol in the urine is difficult and expensive, and thus cannot be used as a test in many cases of early pregnancy of women who have had repeated abortions. Injection of progesterone has been disappointing, perhaps because it produces peak influences followed by 'negative phases,' but by implantation of a 100-mg pellet of progesterone it is possible to preserve an even absorption of the hormone. Unfortunately progesterone is not well tolerated by the tissues, and it is always extruded from a fat embedding. It is possible, however, to increase the chance of its retention by embedding the crushed pellet beneath the rectus muscle sheath. The whole pellet may be extruded even from below the rectus sheath, but in only one case have the fragments of the crushed pellet been rejected. I have done too few cases to generalize, but I have evidence that implantation in suitable cases is at least associated with continuation of an undisturbed pregnancy.

Conclusion

I began the address by emphasizing the difficulties and disappointments of endocrine therapy, and continued to show that few conditions can with certainty be cured. The obvious lesson is that we have plunged too quickly and with too high hopes from the endocrinology of animals to its application in clinical medicine. There are many difficulties in the way of clinical research, but it is badly needed. One of the chief obstacles is the complexity of biochemical assay whereby blood and urine levels of the endocrine secretions and their by-products can be measured accurately. A further field is the quantitative effect of emotional states on pituitary secretions and, as I have said, the role of the receptors of the hormones. The synthesis of stilboestrol is an indication of what great progress would follow the synthesis of other hormones. Finally, except in the case of the 'trace element' iodine and the thyroid the relation of nutrition and other 'trace elements'—the ultimate source of all our secretions—to endocrine activity has yet been scarcely touched.

VOLVULUS OF THE CAECUM

BY

RALPH H GARDINER, DM, MCh, FRCS

Surgeon Royal Buckinghamshire Hospital Aylesbury

While volvulus of the sigmoid colon is a well-known condition, volvulus of the caecum is still classed as one of unusual occurrence, unknown to many members of our profession. Isolated cases are considered worthy of report as rarities, and in standard textbooks of surgery the condition is dismissed in a few lines or else entirely ignored. It is not nearly so uncommon as has hitherto been supposed. I have been able to collect reports of 15 cases in the past five years and have had three personal cases in the past two and a half years and it is by no means a unique occurrence in the experience of other surgeons, many cases not having been reported. It should receive wider recognition as it is a condition associated with a high mortality rate if treatment is withheld for long and is apt to remain undiagnosed altogether until the abdomen is opened—frequently too late. Partial torsion often occurs in recurrent attacks over a period of years, sometimes culminating in an acute complete torsion, and may be the cause of obscure abdominal pain and discomfort, simulating in some cases subacute appendicitis. Furthermore, it can seriously complicate pregnancy and the puerperium, and is therefore of importance to obstetricians. A review of the condition dealing with its diagnosis and treatment will, I feel, be of value.

Mortality Rate and Incidence

Some idea of the incidence of the condition may be gained from a review by Wolfer *et al* (1942) who found that 194 cases had been reported since 1913, with 110 previously, in the world's literature making a total of 304. Mortality rates given are very high—50 to 60% in cases which had been operated on, rising to 100% in those which had not. A wider recognition of the condition, with prompt diagnosis and treatment, should certainly bring this high mortality rate down to a much lower figure.

Anatomical Factors in Causation

Normally, after the process of herniation of the midgut loop into the umbilical cord has taken place, with its subsequent rotation it returns to the abdominal cavity and the process of descent and fixation of the caecum occurs. This is called the third stage of rotation. The caecum lies beneath the liver on its return to the abdominal cavity and then descends to the right iliac fossa, finally becoming fixed to the posterior abdominal wall, its mesentery disappearing. If the fixation, with disappearance of the mesentery fails to take place the caecum and ascending colon are left with a variable degree of mobility depending on the length of this mesentery and it may even be continuous with that of the terminal ileum, making a common ileocaeco-colic mesentery. Variable amounts of ascending colon may be included up to the hepatic flexure and extending to the transverse mesocolon. This will render the caecum and a variable portion of the right half of the colon liable to torsion. The terminal ileum may also be involved. Points of fixation at the base of this mesentery frequently act as hubs round which torsion occurs. Such fixed points are often found at the level of the hepatic flexure or at the point where the transverse colon crosses the duodenum.

Wolfer *et al* investigated the frequency of this non-fixation of the caecum and right half of the colon, and concluded that it occurs in at least 15% of individuals. Other workers give even higher figures—20 to 25%. Any

of these may be liable to caecal volvulus. Rarer causes are errors of rotation (non-rotation, reversed rotation, non-descent of the caecum), several examples of which have been recorded (Dott, 1923, Donald, 1927, Holman, 1940, Godfrey, 1945). The amount of the bowel involved will depend on the extent of the mesentery. Sir Heneage Ogilvie (personal communication) and Haxton (1944) report cases of volvulus of the caecum which had herniated through the foramen of Winslow, indicating the extraordinary amount of mobility which can be present. The direction of the twist appears to be more common in a clockwise direction, although counter-clockwise is by no means unusual.

Aetiology

Fifty per cent of cases are said to occur between the ages of 20 and 40, but it is common in older people, many cases being found after the age of 60. Males seem to be more prone, in the proportion of three to one (Pratt and Fallis, 1927), which is a surprising preponderance, as women more commonly seem to possess the prerequisite of the persistent mesentery. That it occurs more often in the male sex points to exertion or heavy occupations as factors in causation. Men tend to lead more strenuous lives, and many are engaged in heavy work. Other exciting causes are obscure. Trauma certainly plays a part. Violent bodily exercises involving twisting of the trunk may initiate the condition. Sudden or gradual change in the position of the viscera as occurs in pregnancy or the puerperium is undoubtedly important. Other causes given are (1) mesocolic inflammation, (2) dietetic errors, (3) gaseous distension, (4) violent purgation.

Onset and Symptoms

The onset in some cases is sudden, ushered in by violent abdominal pain, vomiting, and constipation, followed rapidly by abdominal distension, showing all the signs of acute obstruction from the outset, death may be rapid, and has been known to occur within five hours of onset (Valentine and Kinnear, 1937). In others, however, it is more insidious and prolonged, and it is in these cases that delay in diagnosis may be extremely dangerous, as unless the condition is known it can be easily missed. This slow type of onset is well illustrated in my own cases and in others reported, especially those occurring during the puerperium. I would therefore divide cases, according to their rate of onset and manifestation of symptoms, into three types.

(a) *Acute* cases coming on within a few hours and showing all the signs of an acute abdominal catastrophe with the signs and symptoms of obstruction. These are either rapidly fatal or are operated on in good time.

(b) Cases *subacute* in onset—giving a history of several hours up to, more often, 3 to 4 days of variable abdominal discomfort and distension with pain and tenderness. The pain may be localized to the right iliac fossa, the condition simulating an appendicitis, or it may be more central, and is quite often epigastric. Temperature and pulse often remain normal throughout. The pain may begin acutely, only to pass off or to become dull and spasmodic. In these cases the past history is of importance, as the patient will nearly always recall similar attacks of a milder nature which have passed off without incident, indicative of a volvulus that has righted itself. Any or all of the following signs may be found on examination of the abdomen.

Tenderness—This is usually present and is localized over the distended gut, an area of peritonitis developing over and around it. This area is often well demarcated, and occurs according to the position in which the gut is lying, which may be in the right iliac fossa centrally around the umbilicus, below the right

lobe of the liver or epigastric. In pregnancy, as the gut is pushed up by the expanding uterus, the position is always high in the abdomen. The gut tends to move towards the midline ultimately, so the tenderness becomes more central.

Distension is generally gross, with a tympanitic note indicative of a large accumulation of gas, but may be slow in manifesting itself. Rectal or pelvic examination may not reveal much, the rectum may or may not be empty, depending on whether the bowels have moved or not. Signs of obstruction will ultimately be present. A plain skiagram of the abdomen is of inestimable value, and is diagnostic in most cases, as pointed out by Chesterman (1945) (see Figs 1 and 2). The greatly dilated caecum casts a clear shadow, but it may be mistaken for the grossly dilated stomach of chronic pyloric obstruction. The case history should exclude this error, which may arise in cases of slow onset, but a small quantity of barium by mouth will indicate the position of the stomach higher up. A barium enema is rarely necessary for diagnosis.

(c) The *chronic* type of case is that in which transient partial volvulus occurs which sooner or later untwists itself. These cases are associated with pain in the right iliac fossa, tenderness, and varying degrees of gaseous distension. One of my cases gave a history of frequent attacks of this nature over a very long period. His abdomen would blow out with wind, gradually subsiding with the passage of a large quantity of flatus. Histories of such attacks are of great importance in diagnosis, as they are often given by patients suffering from complete acute torsion. Special mention must be made of the occurrence of the condition as an acute complication of pregnancy or the puerperium. Norris (1941) reported a case at the fifth month of pregnancy diagnosed four to five days after the onset, and my first case occurred at the fifth month of pregnancy. In Norris's case there seemed to have been a previous chronic attack, and it was first diagnosed as a pyelitis, but a barium enema subsequently showed obstruction at the splenic flexure. Sheldon (1944) and Rose (1941) have reported cases with onset early in the puerperium. Sheldon's case occurred apparently 12 hours after delivery, but was not operated on until the fourth post-partum day. Rose reported a case in a primipara of 38, starting 17 hours after delivery, with a fatal ending, as no diagnosis was made until a laparotomy was done some days after. Rose pointed out the importance of bearing in mind the possible chance of a volvulus being the cause of distension early in the puerperium and he states that the question of exploration of the abdomen should be seriously considered if a post-partum abdominal distension refuses to respond to treatment in 24 hours. He is of the opinion that a volvulus of the caecum or of other parts of the intestine (Spence, 1937) should be listed as one of the causes of post-partum distension, the others being retroperitoneal haemorrhage due to rupture of the uterine artery, puerperal peritonitis, and paralytic ileus.

Treatment

This, of course, is early laparotomy, dealing with the gut according to the state in which it is found when the abdomen is opened. Adequate pre-operative treatment so far as time will allow is of great importance, and blood transfusion should be given, as the volvulus is a type of long loop obstruction with stagnation of a large volume of blood in the distended bowel wall and fluid is lost into the abdominal cavity. Gastric suction and lavage are of value before and after operation. The procedure to be adopted will depend on the condition of the gut. If *viable* (a) derotation with or without fixation of the gut, (b) derotation with caecostomy to decompress and drain the bowel. If *gangrenous* (a) exteriorization and removal with the cautery, with subsequent closure of the artificial anus, (b) resection (right hemicolectomy) and anastomosis of the ileum to the transverse colon.

If early, derotation with or without fixation of the caecum to prevent recurrence, provided it is certain that the bowel is viable, is the best treatment. Fixation can be achieved by Waugh's (1920) method or by less elaborate means, such as removal of the appendix and then fixing the stump to the anterior abdominal wall with a purse-string suture (Lyall, 1946). Caecostomy may also be performed, and is advised by some workers, to drain the distended loop of gut, if done, it should assure fixation by adhesion formation. Very careful handling of the gut is essential owing to its friable and distended state. Later on, if frank gangrene has set in or if the viability of the gut is at all in question, then two methods are available—exteriorization or resection. Exteriorization, with removal by the cautery and subsequent closure of the stomach at a later date, is held by many to be a fatal form of treatment to adopt, associated with a high mortality, but Miller and Clagett (1940) reported two successful cases using this method. Chesterman states that volvulus of the caecum is the only type of obstructive colonic gangrene for which treatment by resection is successful, he recorded one success treated by resection. MacCarthy (1945) reports two cases—one was successful, the other patient died of pneumonia three days after operation. Two of my cases, both of which were in an advanced state of gangrene, were treated by rapid resection and right hemicolectomy with end-to-side anastomosis of the ileum to the caecum, both recovered. The presence of the long mesentery and freely mobile gut makes this, to my mind, an easy procedure. No mobilization of the gut is necessary, and only two to three ligatures on the mesentery are required. If rapidly and skilfully performed, resection is not associated with so high a mortality as has been stated. There remains the chronic case if the diagnosis is certain and recurring partial volvulus is definitely proved to be the cause of chronic abdominal discomfort, should laparotomy and anchorage of the mobile caecum be performed? There are also the large number of cases of mobile caecum from other causes discovered at laparotomy—should fixation be performed as a prophylaxis in these? The choice will depend on the individual surgeon, one is hesitant to advocate a return to the old days of pexis. If the caecum is to be fixed, Waugh's method could be used, but less elaborate procedures would seem to be adequate.

Case I

A married woman aged 37 (R B H 43/795) was admitted to the Royal Buckinghamshire Hospital on April 26 1943 at 10 p.m. with a history of the onset of sudden severe pain in the epigastrium beginning three hours before admission. At 8 p.m. the pain became very severe, and she vomited once. The bowels had been opened normally the same morning. She was six months pregnant, having had three normal pregnancies. One month previously she had had a similar attack of pain in the right groin spreading across the lower abdomen. It was sudden in onset, lasting half an hour, with severe vomiting. The pain suddenly ceased, and the attack passed off completely.

On admission she was pale, thin, and tired-looking, temperature 97° F (36.1° C), pulse 70, tongue clean. The abdomen showed rigidity and tenderness all down the right side. The uterus was enlarged to the extent of a 5½-months pregnancy. Micturition was normal and the urine clear. Per vaginam nothing abnormal was seen except a gravid uterus. No definite diagnosis was made—it was decided to watch her overnight, and her pulse was taken half-hourly. Throughout the night it remained steady at 70 to 75 a minute, but in the early morning the pain, which had been dull during the night, suddenly became very severe. At 6 a.m. the temperature was 98° F (36.7° C) and pulse 75—it was decided to do a laparotomy. The abdomen was opened by a right paramedian incision and offensive free fluid poured out. The caecum, ascending colon, right half of the transverse colon and terminal ileum were found lying on the right side beneath the liver. They were in an advanced

state of gangrene, grey-green in colour, and very offensive. A rapid right hemicolectomy was performed and the ileum joined to the transverse colon by an end-to-side anastomosis. Sulphapyridine, 15 g in warm saline, was placed in the abdominal cavity and the abdomen drained through a right flank incision. The patient made an excellent recovery and was discharged on the 15th post-operative day.

She was readmitted to hospital at midnight on June 23 with a further attack of abdominal pain and vomiting, and a diagnosis was made of small-gut obstruction, possibly due to adhesions. Stomach suction was carried out, and she was operated on a few hours after admission by the late Mr C A Joll. No obstruction was found, and but for a few adhesions around the small gut the abdomen was clear. A classical Caesarean section was performed at the same time and a female child, birth weight 5 lb 11 oz (2.58 kg), was delivered. Mother and child were discharged fit and well on July 11.

Case II

A roadmender aged 59 (R B H 44/678) was admitted to the Royal Buckinghamshire Hospital on April 8, 1944, complaining of abdominal pain. This had begun a few hours previously and was very severe, causing the patient to sweat and feel faint. He had vomited several times, and the bowels, which were usually very regular, had not been opened. He was also suffering from acute retention of urine, and his doctor had found it necessary to pass a catheter for relief. He had been investigated for gastric ulcer some seven years previously.

On examination he was healthy-looking with a good colour, pulse 100, temperature 98° F (36.7° C) and he showed no evidence of shock or collapse. Heart and lungs were normal. His abdomen was slightly distended, and there was tenderness in the right iliac fossa with some rigidity—a diagnosis was made of acute appendicitis or, possibly, a perforated peptic ulcer. He was operated on within an hour or two of admission. The abdomen being opened through a right paramedian incision. The peritoneal cavity contained blood-stained fluid and the right iliac fossa appeared empty. On examining the pelvis, distended and tense bowel could be felt firmly wedged. It was thought to be a volvulus of the sigmoid colon, but on delivery was found to be an enormously distended caecum with a portion of ascending colon and terminal ileum. At one point the caecum was gangrenous and also perforated. A rapid resection was therefore done of the whole of the volvulus, including the terminal ileum, caecum and ascending colon. An end-to-end anastomosis was performed between the terminal ileum and the distal end of the ascending colon. Sulphapyridine 15 g in saline, was placed in the abdominal cavity and also in the wound, and the abdomen was drained. He made an excellent and uninterrupted recovery, and was discharged fully recovered on April 20, 12 days after admission. He returned to work shortly afterwards, and has since been carrying on without trouble.

Case III

A man aged 60, a secretary, was admitted to the Tindal House Emergency Hospital, Aylesbury, on Jan 12, 1946, as a medical emergency. The history was that three days before admission the patient had had a sudden attack of coughing and breathlessness while walking, and was just able to reach home, where he collapsed. A diagnosis of coronary thrombosis was made. Examination had revealed signs of myocardial failure but nothing else definite beyond diminished breath sounds at the base of the left lung. There was also marked swelling of the lower abdomen and tenderness in the left iliac fossa. His bowels had been constipated since admission, and there had been no result from four enemata. Examination showed an empty rectum. On account of marked distension I was asked to see him in consultation on Jan 14 to exclude any possible lesion in the abdomen although the diagnosis of coronary thrombosis was fairly certain. When I examined him he was sitting up in bed having his tea, and made no complaint at all of any abdominal discomfort. Examination of the abdomen revealed marked distension with gas and a tender mass situated in the midline of the lower abdomen which was tympanitic. He stated that he had often had similar attacks, extending back over a number of years, which passed off with the passage of a large amount of gas, and he was suffering no discomfort during

this attack. I diagnosed a possible volvulus of the caecum, and this was confirmed by straight skiagrams (see Figs 1 and 2). He was very loath to submit to a laparotomy, and as there was no doubt that he had a coronary thrombosis and left basal pneumonia, the question of operation was very carefully considered. As there was no sign of the swelling going down the next day and in view of the x-ray findings, I decided to operate in the

FIG 1—Case III. Straight skiagram of abdomen (upright). Note large fluid level across middle of abdomen just above the iliac crests.

FIG 2—Case III. Straight skiagram of abdomen (supine). Note shadow of enormously dilated caecum stretching across abdomen from right iliac fossa to level of first lumbar vertebra on left side.

afternoon. Before the operation started he collapsed under the anaesthetic and the heart stopped beating. The abdomen was opened through a midline epigastric incision and the heart rapidly massaged. The beat returned in about three minutes, and a rapid examination of the caecum before sewing up revealed a complete volvulus involving the terminal ileum and ascending colon. It was blue black in colour, with suspicious areas of ulceration on the surface. It was twisted in a counter clockwise direction, this was quickly undone and the gut was replaced in the abdomen, which was rapidly closed. He was returned to the ward, but never regained consciousness, he died five days later, on Jan 19.

Necropsy showed a thrombosis of the descending branch of the left coronary artery with a large infarct of the anterior wall of the left ventricle. There was venous congestion in the liver and spleen and a patchy bronchial pneumonia at the left base. The caecum and ascending colon were abnormally mobile, with a mesentery which extended halfway up the ascending colon. There was slight kinking of the bowel, the caecum was distended and had fallen forward, and was half rotated to the left. The bowel however, was quite viable and there was no evidence of gangrene.

Summary and Conclusions

Volvulus of the caecum is a far more common condition than has hitherto been supposed.

One or several attacks of partial volvulus often precede an acute and final attack.

Pain and tenderness in the right iliac fossa shifting to the centre of the abdomen, with immediate or subsequent gaseous distension and obstruction, are the usual findings.

Straight skiagrams of the abdomen give appearances which are diagnostic of the condition.

It may seriously complicate pregnancy or the puerperium.

Cases should be recognized early, and the treatment is by laparotomy, dealing with the condition of the gut found at operation, if viable, by derotation and fixation, if gangrenous, by right hemicolectomy.

Three illustrative cases are recorded.

I wish to thank Sir Heneage Ogilvie, KBE, for his kindly advice and comments, and Dr T V Critchlow for the excellent x-ray photographs.

Milk production continues to rise in Britain. According to figures recently given by Mr I L Davies, of the Milk Marketing Board, the estimated output in December was 98,000,000 gallons which is only just short of the target set for December, 1947—100,000,000 gallons. Consumption during 1946 was 53% higher than before the war, and the abolition of milk rationing in England and Wales would necessitate an annual monthly production of 110,000,000 gallons. The ration may be larger next winter—three pints a week is hoped for—but there is no prospect of its being abolished then.

THE HEART IN RHEUMATOID ARTHRITIS

BY

ALFRED S ROGEN, MD, FRFPG

(From the Department of Materia Medica and Therapeutics Glasgow University and the University Medical Clinic Stobhill Hospital)

Rheumatic fever and rheumatoid arthritis are generally regarded as distinct diseases which have much in common, but the possibility of their having a common aetiology has often been discussed. As cardiac lesions are characteristic of rheumatic fever, many workers have sought similar lesions in rheumatoid arthritis. Recently tissues obtained at necropsy from patients who had suffered from rheumatoid arthritis have been studied and a high incidence of heart lesions has been reported showing histological characteristics similar to those of rheumatic fever.

Only the more recent published work will be reviewed here. Master and Jaffe (1932) reported on the electrocardiographic findings in 17 patients with rheumatoid arthritis. The absence of abnormalities—as contrasted with a 100% incidence of electrocardiographic changes in rheumatic fever—prompted them to suggest that when in doubt as to the differential diagnosis between these two conditions a normal electrocardiogram was in favour of a diagnosis of rheumatoid arthritis, but the number of patients was so small that this suggestion must remain a tentative one. Dawson and Tyson (1936) presented evidence to show that the two diseases are intimately related. Their similarity was stressed under the headings of familial relationship, geographical distribution, initiating factors, seasonal incidence, age incidence and clinical manifestations of the two diseases in different age periods, pathological similarities, and immunological findings. In a series of 100 patients they found 7 with unequivocal signs of rheumatic heart disease: the onset of disease in all these patients occurred most commonly in the second and third decades of life. Collins (1937) and Bennett, Zeller and Bauer (1940) reported that the nodules of rheumatoid arthritis and rheumatic fever were not similar on microscopical examination. On the other hand Baggenstoss and Rosenberg (1941) quote various workers who reported the histological similarity of the subcutaneous nodules of the two diseases. Baggenstoss and Rosenberg (1944) described two cases of rheumatoid arthritis with cardiac lesions very similar histologically to the subcutaneous nodules present in that disease. They state further that as a rule, the cardiac lesions of rheumatoid arthritis are indistinguishable from those produced by rheumatic fever. They had previously (1941) found the rheumatic type of heart disease in 14 of 25 cases of rheumatoid arthritis which came to necropsy: in only 7 of these 14 had there been any clinical evidence of heart disease. In 6 the mitral valve was involved, and in 2 of these there was advanced stenosis. Bayles (1943) in 23 necropsies on subjects with rheumatoid arthritis found 6 cardiac lesions suggestive of rheumatic fever: 1 possibly active and 5 inactive. Young and Schwedel (1944) in a post-mortem study of 38 cases of chronic rheumatoid arthritis found cardiac lesions in 33, in 25 of which

given. It was further pointed out that microscopical examination of the myocardium showed Aschoff bodies in one case only, but that this was not surprising as the majority of the patients were old at death. Again, scarring in the myocardium occurring in only two instances was considered to be an unduly low incidence for acute rheumatism. The annotator also made the important observation that “in rather a large proportion of cases clinical examination had given negative results.” This apparent discrepancy between the clinical assessment and the post-mortem findings calls for careful consideration. It suggests that valvular disease may occur in rheumatic fever without producing clinical signs, in which case one could never be sure that there was no valve damage. In other words, the lesions might be demonstrable histologically and yet fall short of interfering with the valve mechanisms. Alternatively, there might be some other fundamental difference between the valvular lesions of the two diseases, so that those of rheumatic fever resulted in the production of murmurs while those of rheumatoid arthritis did not—a state of affairs which is highly improbable. Fraser (1945) noted a 14% incidence of valvular disease of the heart on clinical examination in 110 patients suffering from rheumatoid arthritis. This was merely an incidental finding, however, and the valvular lesions are not classified. Paul D White (1944) states that, in rheumatoid arthritis, pericarditis and endocarditis and myocarditis may infrequently appear as complications not to be ascribed, at least in all cases to a coincident rheumatic fever.

The Present Investigation

The object of this paper is to record the results of a detailed examination of the cardiovascular system in 33 consecutive cases of rheumatoid arthritis admitted to municipal hospitals in Glasgow. The severity of the illness in these patients is given in accordance with the classification suggested by Slater (1943). Of the 33 patients 4 fell into Group I, 10 into Group II, 11 into Group III, and 8 into Group IV. Besides the usual clinical examination every patient was submitted to electrocardiographic investigation. In addition, radiological examinations of the heart were made in the earlier patients of the series, but this was soon found to be impracticable because of technical difficulties associated with the gross deformities of the joints resulting in inability to get many of the patients into the suitable position. None gave a previous history of rheumatic fever.

Eleven of the patients were males and 22 were females. The age distribution is shown in Tables I and II which also give the duration of the illness in each case.

TABLE I—Age Incidence Males

	Age Groups						
	40-45	46-50	51-55	56-60	61-65	66-70	71-75
No. in each group	3	2	2	0	2	1	1
Duration of illness (in years) of each patient	1 4 2	2 3	5 1		6.5 2 14	1 2	1

TABLE II—Age Incidence Females

	Age Groups										
	25-30	31-35	36-40	41-45	46-50	51-55	56-60	61-65	66-70	71-75	76-80
No. in each group	1	3	1	0	1	4	2	1	4	3	2
Duration of illness (in years) of each patient	1/52	8 7 7	5		20	18 35 6 2	8 2	10	3 5 4 9	31 3/12 4	4 10

(65.7%) the lesions were considered to be indistinguishable from those of acute rheumatism and of a non-specific infective nature in the remaining 8. An active rheumatic process was present in 6. There was a history of rheumatic fever in 3 only and of probable rheumatic fever in 2. From this extremely high incidence of the rheumatic type of heart disease in rheumatoid arthritis they concluded that there is an extremely close aetiological relationship between the two diseases.

An editorial comment (*British Medical Journal* 1945, 1, 636) on Young and Schwedel's paper notes that the incidence of disease on the several valves was similar to that of acute rheumatism but that the incidence of mitral stenosis was not

The duration of disease is that given by the patient. No doubt there is considerable inaccuracy here. For example in two patients who gave histories of only a few weeks duration bony changes were apparent on x-ray examination. Accepting the figures as given by the patients however, the average duration of the illness for the males was 3.2 years and the females 9.0 years—long enough for the development of any lesions.

That males were, on the average, admitted to hospital for treatment so much earlier than females is probably accounted for by the fact that in the breadwinner impairment of manual dexterity or locomotion is likely to be of more serious consequence than similar disabilities in the housewife.

The cardiac rhythm was regular in all cases. The first mitral sound was split in 2 cases, and the intensity of this sound was diminished in 10 others, compatible with their age and varying degrees of emphysema, otherwise no abnormality was noted. However, it would be only in the incidence and character of murmurs indicative of valvular disease that a parallel between this disease and rheumatic fever could be drawn. A particularly careful search was made for evidence of early mitral stenosis, but none was found. In 8 cases a faint systolic murmur was heard at the mitral area, in all of these it was sharply localized. None of them was associated with a loud sharp first sound or with an accentuated second pulmonary sound. They were considered to be functional in origin. In one case only was there a loud mitral systolic murmur, it did not replace the first sound but was conducted well into the axilla. This occurred in a woman of 68 who had had rheumatoid arthritis for nine years, and the signs were thought to indicate organic mitral valve disease.

Electrocardiographic Findings

There are, of course, no electrocardiographic abnormalities pathognomonic of rheumatic fever, the study of electrocardiograms in rheumatoid arthritis is therefore of limited value in studying the aetiological relationship between the two diseases. According to Katz (1941) chronic rheumatic heart disease may result in tracings showing preponderance of one or other ventricle resulting from valve deformities, or the appearance of large, broad, or notched P waves associated with auricular hypertrophy. Specific contour changes and arrhythmias may develop, such as frequent auricular premature beats, which are said to be particularly significant when they arise from multiple foci. Electrocardiograms were taken from 29 patients. Left axis shift was present in 17, there was a considerable incidence of slurring of the QRS complexes, and the T wave was inverted in one case in Lead I, in another in Lead II, and in a third in Lead CF. These abnormalities were consistent with the senile degeneration of the coronary arteries of old people, who formed the majority of the patients in this series. None of the records showed abnormal ventricular preponderance, the P waves were well formed, and the cardiac rhythm was unaffected. A woman of 71, who gave a history of only three months' illness but who had obvious joint changes on x-ray examination, showed very low complexes in all leads when the first electrocardiogram was taken. Serial tracings showed an increasing amplitude of the complexes until five weeks later the voltage was well within normal limits. This suggests that there was transient myocardial damage during the acute phase of the illness, but it does not necessarily denote any common aetiological factor between rheumatoid arthritis and rheumatic fever, such findings might be encountered in many acute illnesses and toxic states.

Only one patient in the present series came to necropsy. She was an elderly woman who died of cerebral thrombosis. The naked eye appearances and histological findings in the heart revealed no evidence of rheumatic infection.

Discussion

The results of this investigation serve to emphasize once again the extraordinary discrepancies which exist in the opinions of different workers. No doubt this is largely the result of failure to lay down generally acceptable criteria for the clinical diagnosis of cardiac lesions in the early stages of disease. Another difficulty is that of excluding cardiac abnormalities which are purely incidental and usually the accompaniments of senile degenerative changes in the myocardium and coronary arteries. After making liberal allowances for these complicating factors, it would appear that clinical evidence of mitral valve disease was elicited in only one patient in a series of 33 cases of rheumatoid arthritis. The literature cited raises the possibility that the incidence of subclinical valvular disease associated with rheumatoid arthritis in the present group was much higher than this, but in the solitary case examined at necropsy no cardiac abnormalities were detected. A final opinion on the concept of latent or subclinical endocarditis must await further pathological studies, which will need to be sufficiently comprehensive, the difficulties in the way of obtaining these data in a disease which *per se* is rarely fatal need no emphasis.

Summary

Recent literature on the subject of the aetiological relationships between rheumatic fever and rheumatoid arthritis is reviewed.

Among 33 patients suffering from rheumatoid arthritis only one was found to have a cardiac lesion which might have been attributable to the disease. Another patient came to necropsy, and was found to have neither histological nor naked eye abnormalities of the heart.

A brief reference is made to the limited value of comparisons between the clinical manifestations of these two conditions in the present state of our knowledge of the rheumatic diseases.

I have pleasure in expressing my indebtedness to Prof. Noah Morris and Dr. Stanley Alstead, who assisted me in the preparation of this paper. My thanks are also due to Drs. Briggs and Cunningham, medical superintendents of Stobhill Hospital and the Eastern District Hospital, respectively, for permission to publish.

INCIDENCE OF YAWS AND OF VENEREAL DISEASES IN LANGO (UGANDA)

By

C. J. HACKETT, M.D.

Director, Wellcome Museum of Medical Science, London

During a study of the bone lesions of yaws in Lango the high incidence of that disease became apparent. Since a medical survey was not practical, nor was it necessitated by trypanosomiasis, other measures were sought to ascertain more precisely the frequency of yaws. At the same time the incidence of venereal diseases in Lango and, for comparison, in Ganda was assessed. Medical reports were examined, out-patient attendance records analysed, and a labour force and a sample of a gaol population were studied. These data form the basis of this paper.

The results of a survey for leprosy are contained in the annual report of the District Medical Officer of Lango for 1931. Of 24,249 children under 15 years of age, 963 (3.9%) were suffering from secondary yaws. Of 152 cases of secondary yaws with bone lesions studied by me in 1937-9, 131 (86%) were under 10 years of age. Active secondary yaws in children was observed in practically every Lango community, and chiefly in the younger age groups. The absence of yaws in infants before the age of walking was also noted.

Survey of Out-patient Attendances, Lira and Masaka

Lira (Lango district), about 3,600 ft (1,100 m) above sea level and north of Kampala, is in a part of Uganda described as a "yaws area"—i.e., one in which yaws is common. Syphilis rarely occurs. Masaka (Ganda Province), about 4,300 ft (1,300 m) above sea level and south-west of Kampala, is in a part regarded as a "syphilis area" and in which yaws is infrequent. This characteristic local distinction of the two diseases applies only to the indigenes. Masaka has been chosen rather than Kampala for comparison with Lira, since it is not so large a centre as Kampala, and from it are thus more likely to give an accurate picture of the conditions present in a rural community. The figures in Tables I, II and IV were obtained from the monthly sickness returns for Lira and Masaka, which were based mainly upon the diagnoses of trained African medical orderlies. The diagnoses of the conditions concerned may be regarded as fairly accurate. Orderlies with experience in both yaws and syphilis were working in both clinics.

BLE I—Average Annual Out-patient Attendances by New Cases at Lira and Masaka for the More Frequent Complaints (excluding Coughs Colds and Traumatic Lesions) and for Syphilis and Gonorrhoea

	Lira (1928-36)		Masaka (1930-8)	
	Totals	/	Totals	%
yaws	3 077	20.9	266	1.6
syphilis	164	1.1	2 818	17.5
gonorrhoea	85	0.6	410	2.5
Myalgia	662	4.5	340	2.1
Ulcers	803	5.5	443	2.8
Malaria	775	5.3	1 966	12.1
Ratio of gonorrhoea to syphilis	0.5 to 1		0.15 to 1	
Total attendances (all causes)	14 707		16 207	

The incidence of yaws at Lira was 13 times that at Masaka, while the incidence of syphilis in Masaka was 16 times that at Lira. At Lira the incidence of yaws was 19 times that of syphilis, and at Masaka syphilis was 11 times more prevalent than yaws. Congenital syphilitic infants were frequent at Masaka. Gonorrhoea, however, was only 4 times more frequent at Masaka than at Lira. The proportion of new cases of gonorrhoea to those of syphilis at Lira was 0.5 to 1, and at Masaka 0.15 to 1. This ratio in England and Wales in 1936 was 2.6 to 1 (18th Annual Report of the Ministry of Health). The figures for gonorrhoea at Masaka may be incomplete, since in Ganda Province this disease is prevalent. It is unfortunate that the incidence of gonorrhoea cannot be used as a check on that of syphilis. At Lira "myalgia" and "ulcers" were diagnosed twice as frequently as at Masaka. Malaria was only about half as frequently diagnosed at the former as at the latter, but at both the real incidence probably approximated to 80-100%.

The Medical Officer, at Masaka (Dr A G Mackay) said that most of the yaws cases seen there were in immigrant labourers from the Belgian mandated territory of Ruandi-Urundi, and that the disease was rarely seen in the indigenous Ganda population. At Lira the Medical Officer's annual reports repeatedly state that most cases of syphilis and gonorrhoea occurred in Bantu immigrants (Ganda and Nyoro) and in Kumam people, and very infrequently in the indigenous Lango. Personal observations confirmed this. At Lira, though the total attend-

TABLE II—Sex Distributions of Average Annual Out-patient Attendances for All Causes and for Yaws and for Syphilis at Lira and Masaka

	Lira (1928-36)			Masaka (1930-8)		
	Totals	% of Totals	% of Totals for Sex	Totals	% of Totals	% of Totals for Sex

Males	69	42.0	1.39	1 251	45.0	20.2
Females						

ance by females was only half of that by males, the attendance for yaws by females was nearly equal to that by males. At Masaka the total attendance by females was 60% of that by males, and the attendance for syphilis by females was 80% of that by males. The attendances for both diseases included cases at all ages and all stages. The higher attendance by females for yaws at Lira may in part result from mothers accompanying their yaws infected children to the clinic and presenting themselves for treatment for late yaws lesions. The higher female attendance for syphilis at Masaka may partly arise from women being more alert regarding early secondary skin lesions. The figures in Table III were obtained by the then Director of Medical Services of Uganda (Dr W H Kauntze). It will be seen that at Lira the yaws cases were a random sample of all other attendances. At Masaka fewer children attended the out-patient department than at Lira, the smaller number of

children among the syphilis cases compared with those among all other cases is statistically significant (6.6 ± 3.12). This stresses the higher ages of the syphilis patients.

In Table IV the variations in the average monthly attendances for yaws are statistically significant. The figures for males and females closely resembled those for the sexes combined. The variations in the average monthly attendances for syphilis at Masaka were not statistically significant. It will be seen that the peaks of maximal incidence of yaws were in April and October, and that there were ascending peaks for the total attendances less yaws in March-April, July, and October-November.

From Table V it will be seen that there is some slight relationship of yaws incidence with an average monthly rainfall over 6 in (15 cm) and an average relative humidity at 14.30 hours over 50%. An analysis of the community activities of the Lango, however, suggests that the attendance peaks under consideration coincide with the slackest periods of local husbandry—between the planting and harvesting of early and late crops.

Out-patient Attendances, Kampala

From the out-patient record cards at Mulago Hospital, Kampala, for attendances during 1933 and 1934, notes were made in 190 cases diagnosed as secondary syphilis. This is

only a small proportion of the total attendance for that disease, but these records, mostly of Ganda patients, were chosen for their relative completeness. In 173 of these 190 cases (all young adult males) the serum Kahn was positive or spirochaetes were found. In 7 the serum Kahn was negative. Penile sores were present in 60 cases, 41 admitted and 6 denied having had any penile lesions. Among these 190 cases the following frequency of lesions was recorded: condylomata, 91, secondary rashes, 21, macules, 20, papules, 14, maculo-papules, 9, circinate lesions on scrotum, 8, buccal mucous membrane lesions, 8, papulo-squamous, 3, squamous, 2, circinate, 2. The condylomata were described as scrotal, perineal, and anal. No mention was made of any framboesiform lesions. At Lira the atypical secondary yaws lesions, and genital lesions, in the absence of typical lesions were infrequent. Loewenthal (1939) reported syphilitic aortitis and aneurysm, meningo-vascular lesions, choroiditis, and gummatous iritis in patients at Mulago, but stated that visceral gummata were rare. Such lesions were not seen among the Lango.

Serological Surveys

Sera collected in January, 1939, from 100 consecutive male Lango prisoners, aged 18 to 35 years, in the Erute (Lira) Gaol gave the following Kahn reactions: + + + +, 46, + + +, 21, + +, 14, +, 2, \pm , 7, and -, 10. If reactions of +, \pm , and - are regarded as negative, then 81 were positive. The ages of these subjects were: 18-20 years, 32, 21-25, 36, 26-30, 23, 31-35, 9. Other findings in this group and in 130 station labourers are given in Table VI.

TABLE VI—Clinical Findings in Two Groups of Adult Lango Males at Lira

	100 Prisoners	130 Station Labourers
History of having had yaws	94	90
Scars of previous secondary yaws	78	79
Enlarged epitrochlear glands	72	69
Bone changes	68	62
Palmar changes	51	60
Plantar changes	61	73
Bone pain	49	41

One case each of dorsal ganglion of the wrist, Dupuytren-like contractures of the fingers, and aortic systolic murmur was seen among prisoners under 30 years of age, the sera from these were Kahn + + + +. Among the labourers were 4 cases with ganglion and 12 with Dupuytren-like contractures. Bone changes consisted mainly of bowing, thickening, or irregularity of tibiae. Palmar and plantar changes comprised thickening, localized or generalized erosion, fissuring, pitting, and laminar desquamation.

Among the prisoners no statistical association was found between any of the items in Table VI and the reaction of the serum Kahn. The six prisoners who denied having had yaws were under 25 years of age, the serum from two was Kahn + + + +, from another two it was Kahn + + +, and from the remaining two Kahn -. The last two subjects were 20 years of age, both complained of bone pain, one had enlarged epitrochlear glands, and the other had indefinite minor plantar changes. Of 120 male Lango prisoners in the Erute (Lira) Gaol, in October, 1938, 8 denied having had yaws. Their ages ranged from 17 to 33. Sera from four were Wassermann + + + + and Kahn + + + +, those from the remaining four were Wassermann -, from one of these it was Kahn +, from another Kahn \pm , and from the remaining two Kahn -.

Summary and Conclusions

In 1931 a survey showed that 3.9% of 24,249 children under 15 years of age were suffering from secondary yaws.

At Lira, in a 'yaws area,' yaws was a frequently diagnosed disease (20% of 14,707) and was 19 times as frequent as syphilis. At Masaka, in a 'syphilis area,' syphilis was a frequently diagnosed disease (17% of 16,207) and was 11 times as frequent as yaws. At each locality coughs, colds, and traumatic lesions were the most frequent diagnoses. Malaria was probably of nearly universal incidence in both localities. At Lira females were proportionately more numerous among the yaws cases than among the total attendances. A quarter of the yaws cases were under 10 years of age. There

was a smaller proportionate excess of females among the syphilis cases at Masaka as compared with the total attendances. Syphilis cases at Masaka were older compared with the age distribution of the other attendances.

In 1939, 81 of 100 consecutive male Lango prisoners, aged 18-35, had positive Kahn reactions. Of the six of this series who denied having had yaws, only two had completely negative Kahn and Wassermann reactions in their sera.

It may be concluded that the incidence of yaws in Lango was high, and that probably very few adults died without having contracted the disease. On the other hand, in Lango the incidence of venereal disease was very low.

The material for this paper was obtained during 1937-40 while holding a Senior Fellowship in Tropical Medicine of the Medical Research Council. I am indebted for much help received to Dr W. H. Kauntze, then D.M.S., Uganda, and his medical officers. All serological tests were carried out by the staff of the pathological laboratory at Mulago Hospital. Dr W. J. Martin, of the Statistical Department of the Medical Research Council, has kindly carried out the statistical analyses.

EFFECT OF ORGANIC MERCURIAL PREPARATIONS ON DISEASES OF THE SKIN

BY

E. A. J. BYRNE, MD, MRCP
Late Medical Specialist R.A.M.C.

A preliminary report on organo-mercurial treatment of the dermatomycoses and of infected skin lesions including 'jungle sores,' was published in the *Indian Medical Gazette* in August 1944 (Byrne and Croxon). This present report is an amplification, and is based on the treatment of 500 cases of skin lesion in the Tropics with organo-mercurial compounds. Three preparations were used—phenyl mercuric chloride, acetate and benzoate, they will be referred to subsequently as PMC, PMA, and PMB.

The toxic action of mercury on bacteria depends on the free concentration of Hg ions in solution (Paul and Prall, 1907), and it has been shown that the Hg cation is the most effective of the heavy metal cations (Woodruff and Bunzel 1909; Winslow and Hotchkiss, 1922), but though the inorganic salt of mercury have a powerful action *in vitro* their bactericidal effect is greatly diminished *in vivo* especially in the presence of organic matter. Chick and Martin (1908) consider that this is due to the fact that the Hg cation combines with protein to form an insoluble albuminate, hence the concentration of free ions is greatly diminished. The same workers reported that the addition of 3% of faeces to a solution reduced the activity of mercuric chloride by 90%. The activity of certain organo-mercurials under these conditions is reduced only by 20-25%, for it appears that the formation of an insoluble albuminate does not obtain to any marked degree with drugs of this group. It therefore follows that in the presence of organic protein matter the organo-mercurials possess a far greater bactericidal effect than do the inorganic salts of mercury.

An exceptional toxicity towards all forms of life is exhibited by those compounds of mercury which structurally are the most simple, and this lethal action is markedly selective in highly organized animals. The effect is determined largely by the character of the hydrocarbon radicle—aromatic or aliphatic—associated with the mercury atom. Aliphatic compounds being particularly virulent. On the other hand, aromatic derivatives have a relatively low local and systemic toxicity, and, provided the hydrocarbon is an unsubstituted phenyl radicle (C_6H_5), very high bactericidal potency.

It is important to record in connexion with specific action that the aliphatic organo-mercurials exemplified by mercuric dimethyl and diethyl— $(CH_3)_2Hg$ and $(C_2H_5)_2Hg$ —and derivatives thereof, such as the chloride (CH_3HgCl) and nitrate (CH_3HgNO_3), have a specific effect on the CNS causing rapid degenerative lesions in cerebral and cerebellar areas. These compounds are most interesting in human toxicology.

view of the long latent period between their application or ingestion and the development of signs and symptoms in the CNS. This characteristic has received much attention in industrial medicine, as the pathological symptoms differ from those associated with ordinary mercurialism (Hunter *et al* 1940, Hill 1943).

Preference for P M C

The aromatic aryl compounds (phenyl mercuric chloride, mercurate borate acetate benzoate and picrate) have been investigated chiefly in the United States, but Biskind (1935) has given a detailed account concerning them in the English literature. Certain of the above-mentioned compounds find extensive application in horticulture and agriculture for the control of fungous disease of plants and the fungicidal action of P M C was investigated by Shaw and Montgomery (1941, Shaw and Moore 1944). They showed that this substance is one of the most powerful fungicides known, and acts rapidly and effectively in high dilution, destroying both spores and vegetative forms.

For medical purposes the bactericidal and bacteriostatic action of P M C was first investigated by Weed and Ecker in 1933. These workers found that the concentration necessary to inhibit the growth of *Str. haemolyticus* and *Staph. aureus* was of the nature of one part in several millions. This effect is due to the C_6H_5Hg ion, and though the solubility of P M C is very low this does not detract from its effectiveness. The ethal effect is due to the action of mercury in combining with and blocking essential thiol groups in the cytoplasm of the infecting fungi or bacteria. The gross disturbance of metabolic function so caused leads to the rapid death of the infecting agents.

P M A and P M B have a marked affinity for chlorine, as NaCl is an invariable constituent of tissue fluid it was felt that the change to P M C would be a rapid one and that the direct application of this ultimate chemical product should be made whenever possible (FitzGibbon personal communication). This report therefore deals mainly with the action of phenyl mercuric chloride.

As in all bactericides the reaction velocity of P M C depends on its concentration in the area in which it is to exert its action but owing to its tendency to produce a vesicant effect on tissue or skin (although strikingly less than other compounds in the series) the concentration used must be carefully limited. In practice it has been found that 0.25% P M C or P M A represents the maximum concentration which can be used without producing these effects. Applications of a much lower strength were used in the majority of cases treated. A strength of 0.5% P M C precipitated on a calamine filler was used in the preparation of an adhesive lotion for moist skin lesions. But the physicochemical mechanisms obtaining when the drug is presented in this way are entirely different from those which occur when emulsifying or aqueous vehicles are used. The use of a colloidal solution was considered, but the grave disadvantage of this method is that in using colloidal solutions of a drug the activity of which is an ionic property the protective colloid removes the charge from the active cation and hence nullifies its effect.

Preparation for Use

In order to deal with the varying types of skin lesions requiring treatment it was decided to present P M C and P M A in three types of base: (1) in eucern and distilled water; (2) in an adhesive lotion of the lotio calaminae type; (3) in simple solution in distilled water. As P M A is soluble in hot distilled water up to a concentration of 2.5% the ointment is made by dissolving the drug in distilled water at a temperature of 85° C. This solution while still warm is slowly added to the eucern previously melted and kept at a temperature not exceeding 55° C. The mixture is continuously stirred until cooled to a white homogeneous cream is produced which is absorbed by the skin with the minimum of friction. In the earlier cases treated a strength of 0.2% was used, but it was later found that 0.125% ointment gave equally good results, and this was employed in the majority of cases. As the solubility of P M C in water is only 1/20,000 the most efficient method is to incorporate the drug in the melted

eucern at 55° C, using careful trituration, and keeping the contents of the mortar heated to 55° C by means of a water bath. It is essential that the P M C be as evenly dispersed as possible in the melted eucern before adding the distilled water (heated to 85° C) in small quantities with rapid stirring. The whole is now allowed to cool rapidly, stirring until a white homogeneous cream is obtained. In the preparation of large quantities the use of a homogenizer would be a great advantage.

For moist surface lesions an adhesive lotion was prepared designed to fulfil the following requirements: (a) Sufficient concentration of P M C to exert the maximum fungicidal and bactericidal effect; (b) contact with the affected area for a prolonged period in spite of excessive perspiration or moistness of the skin; (c) ease of application. It was found that the P M C-calamine preparation was much more 'dense' than calamine B P and required a large amount of zinc oxide and glycerin to maintain an even suspension when shaken and sufficient adhesiveness when applied to the infected area. The following lotion was found to be the most satisfactory:

P M C 0.5% precipitated on calamine	gr 15 (1 g)
Zinc oxide	gr 30 (2 g)
Glycerin	℥ 30 (18 ml)
Distilled water	to 1 oz (28.4 ml)

For large infected areas of deep-seated origin and for 'jungle sores' application of a solution of P M A had the desired effect. A concentration of 1/8,000 was found to be the most efficient. Solution is effected by heating up 2 g of P M A in 250 ml of hot distilled water, and pouring the almost boiling solution into 750 ml of cold distilled water. This stock solution can be regarded as 0.2% w/w or w/v for all practical purposes. The desired strength of solution may then be obtained by further dilution with distilled water. The concentrated solution is self-sterilizing.

Method of Application

At the beginning of the investigation cases were treated as out-patients attending twice daily forunction. Though results were very satisfactory, it was found that this method was wasteful in the use of the limited amount of ointment available at the time. As the reaction velocity of P M C depends on the concentration applied and the duration of application it was obvious that a great saving in the amount of ointment used would be effected by applying it on lint and bandaging it on to the affected part for a fixed period. Investigation showed that three to four hours application of 0.125% strength was sufficient to overcome the infection in all cases of tinea cruris, corporis, and capitis. The affected areas were slightly red and itching for about 24 hours after the treatment. At the end of this time the lesion began to fade out, and in five to six days the skin became normal in appearance, though some slight desquamation usually occurred. In a few resistant cases a second application (of 0.2% strength) was used for three hours.

The types of mycotic infection seen varied enormously, presumably due to the nature of the infecting fungi and the skin reaction of the patient. Dry superficial circinate lesions of large extent and rapid spread alternated with those producing agminate folliculitis and maculo-papular lesions of both guttate and punctate varieties were found. Epidermophyton infections affecting the groins, palms and soles were extremely common as the warm humid climate of SE Bengal and the Arakan areas kept the skin continually moist providing optimum conditions for the growth of fungi.

For all lesions which were reasonably dry a three- to four-hours application of P M C ointment on lint was used. At the end of this time the excess of ointment was wiped off. Where the lesions were moist, application of the ointment was followed by the P M C-calamine lotion. In two to three days the infection was controlled and rapid healing ensued.

Treatment of Various Infections

The following is a classification of the diseases treated by organic mercurial compounds:

Ringworm of trunk and limbs	200
Epidermophyton inguinale	110
Epidermophytosis of feet	90
"Jungle sores"	50
Infected wounds of various types	50

Epidermophytosis of Feet—The interdigital spaces were thoroughly cleaned, and all dead skin removed, 0.5% P M C-calamine powder was applied if the affected area was very moist, and when drying had occurred 0.125% ointment was applied twice daily.

Epidermophyton Inguinale (Dhobi Itch)—A single application of ointment was used for four hours' contact. After thorough inunction into the affected area, paying special attention to the infected spreading edge, strips of lint coated with the ointment were applied to the lesion, and fixed in position with pads of cotton-wool and a double T-bandage. The skin became normal in five to six days.

Regarding epidermophyton infection of the toes, recurrences are mainly due to (1) fresh infection from an outside source, (2) reinfection from the patient's own socks or footwear. To overcome the latter, socks should be steeped for an hour in 1/20,000 P M A solution before washing, the boots or shoes can be treated by spraying the interior with a 1/2,000 alcoholic solution of P M A.

Jungle Sores—In forward areas and where the sores were small or of recent origin, compresses of 1/8,000 P M A were applied for 24 hours. This brought about complete disinfection of the sore. Elastoplast was then applied, after painting the surrounding skin with the solution, and very good results were obtained. In base areas, where large chronic sores were seen, the following technique was adopted: (1) Disinfection with 1/8,000 compress of P M A for 24 hours, (2) normal saline compress for a further 24 hours, (3) skin-grafting on the third day. In some of the early cases the grafts did not take well, and it was considered that excess of the C_6H_5Hg ion was the inhibiting factor. The saline lavage and compress for 24 hours did away with this side-effect. It is suggested (Fitz-Gibbon) that a rapid lavage with a 1% thiourea solution would produce the same effect, as the —SH group in thiourea would neutralize any excess of the compound ion.

Toxic Effects

No cases of sensitivity to organo mercurials were encountered. In some patients especially those of fair or auburn colouring, slight and temporary vesication occurred, mainly around the spreading edges of the skin lesions. This disappeared in 24 to 48 hours, leaving a clean healthy skin beneath. There appears to be no possible danger of toxic effects due to absorption through the skin. The work of the U.S. External Products Research Institute has shown that the body can deal with daily several thousand gamma of Hg in the form of a soluble mercurial, and that the human skin absorbs only 1/3,800 of that applied to it (*American Perfumer and Essential Oil Review* 1943, Stock, 1938). No dangerous mercury reservoirs are formed, as in the case of lead. Ten grammes of 0.125% P M C contains about 6,000 gamma of Hg, and the amount absorbed is minute. In this connexion it is interesting to note that all U.S. reconstituted plasma contains 12.5 mg of phenyl mercuric borate to each 250 ml unit, this is equivalent to about 8,000 gamma of Hg. No toxic effects have been reported in cases which have had large plasma transfusions, in spite of the considerable intake of organic mercury.

Summary and Conclusions

A report is presented of the successful treatment of 500 cases of skin disease by organic mercurials.

It is pointed out that phenyl mercuric compounds in plant mycology are recognized as possessing specific and rapid fungicidal effects in high dilution, and that similar effects can be obtained in fungus infections in man.

The bactericidal potency of these compounds is extraordinarily high, and as surface antiseptics they were found to be extremely satisfactory.

The method of preparation is described, with the results of treatment in certain infections.

It must be emphasized that the method of application and duration thereof must be strictly adhered to in order to effect rapid cure.

The original report was published by kind permission of Medical Directorate, G.H.Q., India Command, and acknowledgments were made to Col P. D. Johnson, R.A.M.C., at whose unit most of the preliminary work was done. My thanks are also due to Mr M. FitzGibbon, F.R.I.C., Lunevale Products, Lancaster, for generous supplies of the organo mercurials mentioned, and for helpful

suggestions regarding certain technical details. I am also indebted to Mr H. Fine, M.P.S., and to Mr J. H. Croxon for their work in the preparation of the applications used, and their help in the carrying out of treatment.

Medical Memoranda

Lethane 384 on Clothing as a Mosquito Repellent

In 1942 during field tests with various antimosquito repellents a few tests were carried out with 'lethane 384'. They were only preliminary tests and were never followed up, but they showed that lethane 384 applied locally to clothing—for example stockings—may have its uses as a mosquito repellent in civil life when dimethyl phthalate either is not procurable or its use is undesirable because of its solvent properties on plastics, paint, etc. Lethane 384 is of course unsuitable as a skin application on account of its irritant and toxic properties.

METHOD

All tests were made in a wood at Brookwood, Surrey, during August, 1942. The mosquitoes biting were mainly *Aedes cantans*, *Ae. punctor*, *Ae. annulipes* with an occasional *Ae. cinereus*, *Ae. geniculatus* and *Anopheles claviger*. Treated volunteers and untreated controls sat together in the wood, usually for 15 minutes, and counted the number of bites experienced. Controls and treated men sat a few feet apart. There were two sets of experiments.

Test 1—Men wore thin cotton stockings (A.T.S. issue), which were sprayed with 50% lethane 384 (25% actual, solvent, a light oil, spray base 775) from a hand spray held at a distance of 1 ft (30 cm). Six pumps were given to the front and six to the back of the legs of each man—23 ml was used to spray four men. The men then rolled up their socks over the stockings at the ankle, pulled down the trouser legs of the bottle dress and waited strolling about, till the testing times. At the test, the trouser legs were rolled up above the knees and the socks turned over below the ankles, and the men sat on the bank of a dry ditch, together with control (stockings untreated), and counted the mosquitoes which bit the legs from knee to ankle. The hands and face were covered with gloves and veils.

Test 2—Men wore denim overalls which were sprayed thoroughly all over so that the overalls could be seen to be wetted. The spray was held at a distance of about 18 in (45 cm). The mean dosage was not less than that delivered on the legs in the first test. In the test the sleeves were rolled up to above the elbow and the number of bites on hands and forearms were recorded. The exposed parts were in no way treated.

RESULTS

Table I summarizes the results for sprayed stockings. The figures in brackets show the number of men in each group.

TABLE I

Time after Spraying (hours)	Period of Test (mins)	No. of Bites		Biting Rate (No. of bites in control = 100)		Protective
		Treated	Control	Treated	Control	
1-1½	15	3 (4)	6 (4)	50	100	88.5
1½-2	15	1 (4)	28 (4)	3.6	100	
2-4	15	1 (4)	35 (4)	2.9	100	97.1
4-5½	15	6 (4)	22 (4)	27.3	100	
5½-5½	15	3 (4)	19 (4)	15.8	100	78
Total		14 (20)	110 (20)	12.7	100	

Stockings removed rolled up and put on again next morning

24	15	24 (3)	23 (3)	104.3	100	Nil
----	----	--------	--------	-------	-----	-----

No. of bites per man

Mean 0.70

S.E. of mean 0.2012

Difference of means is statistically significant

It is evident that lethane on thin fabrics such as stocking material is a very effective repellent, and it has a useful effect for a number of hours. If a bigger dosage was given, probably a even higher degree of protection might ensue for a longer time.

The second test was made in order to see if a complete spraying of the clothing would protect exposed parts which were otherwise unprotected—for example, hands and face

TABLE II

Hours after Spraying	Test Period (mins)	No. of Bites		Biting Rate	
		Treated	Control	Treated	Control
-1	15 15 15	1 (4) 1 (4) 0 (4)	14 (4) 6 (4) 9 (4)	<i>A. claviger</i> mainly	
Total		2 (12)	29 (12)	7	100
-2	15	2 (4)	0 (4)

1-4	30 15 15	1 (4) 0 (3) 0 (3)	4 (4) 0 (3) 7 (3)		
Total		1 (14)	11 (14)	9	100
4-5	30 15	15 (4) 5 (3)	9 (4) 2 (3)		
Total		20 (11)	11 (11)	182	100
5-6	15 15 15 30	0 (4) 3 (4) 1 (3) 6 (3)	1 (3) 0 (4) 2 (3) 4 (3)		
Total		10 (17)	7 (16)	134	100
6-7	15 15 15	0 (4) 0 (4) 0 (3)	14 (3) 10 (3) 7 (3)		
Total		0 (11)	31 (9)	0	100
Grand total		49 (71)	104 (65)		

No. of bites per man 0.69 1.60
S.E. = 0.1650 0.2290
Difference of means is statistically significant

From the results shown in Table II it is evident that no great protection is afforded, and that spraying the clothing is not a reliable method of protecting exposed and otherwise unprotected parts of the body. Sometimes the controls were bitten more often and sometimes the treated, but on the whole as shown by the grand total, a degree of protection is given. This does not bear an obvious relation to time over a seven-hour period.

From these preliminary tests it seems that lethane shows considerable promise in affording protection to those parts of the body immediately underneath the treated cloth, but that it is unreliable if a general protection by spraying all the clothing is required.

I acknowledge with thanks the grant received from the E. L. Hamilton Memorial Fund at the Ross Institute to enable me to prepare wartime work for publication. Thanks are also due to the Director of Hygiene, the War Office, for his permission to publish these results.

Ross Institute of Tropical Hygiene

New Westergren Technique

The following technique for the Westergren sedimentation rate has been found useful. It is simple once it has been mastered; it avoids the necessity of putting lip to tube and is of value when only a few tests are made—for example, in the ward or consulting-room.

A 2 ml. or Westergren syringe is used and the sodium citrate is drawn up to the approximate mark—i.e. 0.4 ml.—the blood is then drawn up to the 2 ml. level and the needle withdrawn from the vein in the usual way. The plunger is pulled out to the full range giving an air space in the syringe. By rocking the syringe, with the needle attached the blood and the citrate are mixed. The syringe, with the needle still attached, is then

held vertically with a small piece of cotton-wool over the orifice, and all air bubbles are expelled.

The syringe is held in the right hand between the tips of the index and middle fingers, with the thumb on the plunger (a stiff syringe is better controlled by holding it between the tips of these fingers and the thumb, with the plunger held against the base of the index finger, and using a squeezing motion). The sedimentation tube is held between the thumb and the last three fingers of the left hand, leaving the index finger free to cover the end. Both the tube and the syringe are held horizontally, the tube may need a slight downward tilt, and the needle is introduced 2–3 mm. into the tube, using a little rotary action of the needle at the orifice to smear the blood round the lumen, the plunger is now pressed home slowly. The blood will run up the tube, on reaching the 200 mm. mark the index finger of the left hand immediately seals the orifice. The needle is then withdrawn and the tube placed in the rack.

It is essential to have a clean tube, otherwise the blood will leave bubbles along the sides and will not run up the tube. I use a small pledget of wool pushed through the tube by two common wooden aural applicators.

E. H. HUDSON, M.B., F.R.C.P.

The "Innocent" Systolic Murmur

The following example may be of interest as testifying to the 'innocence' of a certain type of systolic murmur, remaining unchanged and symptomless over a period of 26 years.

CASE HISTORY

A solicitor aged 30 consulted me on July 13, 1920. He stated he had made several attempts to enter the Forces during the war of 1914–18 and had been rejected by no fewer than five medical boards in turn on diagnosis of V.D.H. and congenital heart disease. Alarmed at this he sought to know his true position and how to order his future life.

His previous history was uneventful. He gave a vague statement of having rheumatic pains during school-days, but had no serious illness of any kind. He had led a normal active life from childhood, through adolescence, to manhood, and was completely unconscious of any symptoms referable to the heart.

On examination there was no clinical enlargement of the heart, the apex was well within the nipple line. No thrill could be felt. There was a loud rasping systolic murmur heard over the whole praecordium, maximal over the pulmonary area. The murmur varied slightly on respiration but not on change of posture, and ended in a curious 'click' suggestive of an exocardial origin. The pulse rate was 84 (nervous under examination), blood pressure 140/80, and the response to an exercise test was good. I gave the opinion that his murmur had no pathological significance, and advised him to ignore it and carry on his normal life—an opinion which was corroborated subsequently by Prof. Wardrop Griffith of Leeds.

I saw him again over a year later, on Nov. 16, 1921, when he was contemplating insuring his life. I found his condition unchanged, and advised him to propose for insurance. He did so, and was accepted with a premium loading of 10%.

Recently, 26 years later, I have had the opportunity of examining him again, on July 22, 1946. Now at the age of 56, he leads a life of normal activity for a man of his years and has no discomfort or distress with moderate exercise nor any symptoms attributable to the heart. The physical signs remain unchanged, no enlargement of the heart, no thrill, systolic murmur loud and rasping, as before, with the same curious terminal click. Pulse rate 96, B.P. 170/80 (heart under nervous excitation due to examination).

COMMENT

During the first world war many similar cases having an innocent systolic murmur were turned down as unfit for service, labelled V.D.H., and suffered a lifelong disability in consequence. In the recent war the insignificance of this murmur has been widely recognized by medical boards. Nevertheless from experience gained in service as medical specialist on pensions boards it would seem that not a few cases have slipped through the meshes of the net.

INHALATION THERAPY

Principles and Practices of Inhalational Therapy By Alvan L. Barach, M.D. (Pp 315, 59 illustrations 25s) Oxford Blackwell Scientific Publications

The author of this book has devoted his professional life to the study of oxygen therapy and allied topics, and he now gives a clear and practical account of these forms of treatment. The book begins with an interesting description of the historical background of inhalation therapy, which has developed in parallel with advances in chemical knowledge. Although the prophet Elisha may be regarded as the pioneer of inhalation therapy, efficient methods of administering oxygen were not developed and popularized until it became necessary to treat large numbers of men with pulmonary oedema caused by gas poisoning in the first world war. The demands of high flying in the second world war have meant a similar advance in oxygen therapy and it is a pity that so little of this is reflected in Dr Barach's book, presumably owing to secrecy regulations. Never was there an age in which men were more reluctant to turn swords into ploughshares.

It is common knowledge that the efficiency and comfort of oxygen masks have been greatly improved, and it has been suggested that the decompression chambers which were used for the training of Air Force pilots would be of great value in the treatment of asthma by pure oxygen at low pressure. Dr Barach proceeds to discuss the use of inhalation therapy in different morbid conditions, devoting most space of course to diseases of the heart and lungs. Like most of those who have actually worked with oxygen he is sceptical of some of the theoretical arguments which have been used against oxygen therapy, and in particular he believes that the frequency of arterial anoxaemia and tissue anoxia in heart disease has been underestimated. It is more troublesome to give oxygen than digitals, and it may well be that some of us have rationalized our desire to avoid trouble.

Barach's personal contributions have been particularly related to the use of helium and positive pressure. Helium is not likely to be a practical proposition in this country, but positive pressure devices can be very simply arranged and are of the greatest value in the treatment of asthma and pulmonary oedema. Positive pressure cuts down the venous return to the heart and has much the same effect as a venesection in heart failure. It seems likely that the expiratory grunt of pneumonia is Nature's way of trying to obtain a positive pressure. The last quarter of the book consists of descriptions of various types of apparatus and simple methods of analysis. Oxygen tents have been rendered much less fearsome by the introduction of transparent canopies for adults and open-top tents for children. Inhalation therapy in the narrow sense of inhalation of vapours of adrenaline and sulphonamides is also considered, but this section unfortunately appears to have been written before the introduction of penicillin and streptomycin.

This book has been written for the practising clinician, and there is nothing in it to repel those who have forgotten all their physics and have left physiology a closed book. Oxygen is the most urgent and least advertised element for the maintenance of life and our patients might get on better if we thought less about vitamins and more about oxygen. The book is well printed and illustrated and can be strongly recommended to all who are engaged in the treatment of acute illness or the provision of facilities for that purpose.

SIR JONATHAN HUTCHINSON

Jonathan Hutchinson: Life and Letters By Herbert Hutchinson (Pp 257, illustrated 12s 6d) London William Heinemann Medical Books Ltd 1946

This is the life history of a remarkable man, the like of whom it is improbable we shall see again. It is written from a sense of family piety by a nephew who is not a medical man but who among much that throws a charming light on his private life, gives full prominence to Hutchinson's unique position in the profession of his time. As Mr Johnston Abraham, who

knew him, says in a foreword, 'he was world-famous as a dermatologist and a syphilographer, an ophthalmologist and a pathologist, besides being a good general surgeon and an authority on neurology.' This seems enough for fame, but he was also an F.R.S., President of the Royal College of Surgeons, the recipient of many honorary degrees, author of countless papers in medical and other journals, author of several important books, was for a year Editor of the *British Medical Journal*, was the originator of the Pathological Museum which is a regular and popular feature of the Association's Annual Meeting, was for 23 years on the surgical staff of the London Hospital, and during part of that time on the staffs of the City of London Hospital for Diseases of the Chest, the Metropolitan, Blackfriars Skin and Moorfields. At one time or another he was president of every one of the leading medical societies of London, and seems to have lectured in almost all parts of the country on medical and other subjects. This formidable list by no means exhausts all his activities. He founded the New Sydenham Society, which over a period of years published translations of important Continental medical books. As a teacher he had a great reputation, as was testified by many, including Sir Frederick Treves. His work as a pioneer in postgraduate medical education deserves special mention. He was well in advance of his time, and the Polyclinic, well known for some years as a centre of advanced instruction, failed probably because it was attached to no hospital. As a clinician he was supreme. Osler said that no individual in this country has made so many useful observations upon so many diseases. Hutchinson is a standing proof that hard work is no obstacle to the attainment of a ripe old age. When he died within a month of his 85th birthday, though he had retired from practice for some years, he was still active with one of the main interests of the latter half of his life, namely, a new kind of museum, an educational museum into which he had put an immense amount of work and from which he obviously got great pleasure. He built and founded two of them, one at Haslemere, his country residence, and one at Selby, his birth place. A great authority on the subject wrote that Haslemere was 'the one effective educational museum in this country.' It is good to know that this incredibly hard worker had a very happy family life. He was one of a large Quaker family and had ten children of his own. This book deserves a warm welcome from our profession and from all who like to read of life well spent.

DIFFICULT LABOUR

The Management of Obstetric Difficulties By Paul Titus, M.D. Third edition (Pp 1,000, 426 illustrations, 8 coloured plates 50s) London Henry Kimpton

There is more in this excellent book than meets the eye. Its title is perhaps a little misleading, for as the reader soon discovers, the author is so enthusiastic about his subject that he includes much more than one would expect to find under the heading of obstetric difficulties. There are, for example, sections dealing with sterility, its investigation and treatment, the diagnosis of pregnancy, ante- and post-partum care, general systemic diseases complicating pregnancy and the puerperium, and a section dealing with the newborn infant which discusses among other things such subjects as the indications for craniotomy and the relationship of erythroblastosis to icterus neonatorum. Those sections dealing with dystocia, haemorrhage, puerperal complications, and obstetric operations are familiar to readers acquainted with the two previous editions of the book. They have been revised in the light of new discoveries such as penicillin and the Rh factor, and modified in accordance with an added experience of x-ray pelvimetry, caesarean anaesthesia, and various operative techniques such as extraperitoneal Caesarean section.

It is refreshing to find that in a work such as this the emphasis is still placed on clinical judgment even while the accessories to diagnosis are carefully recorded and assessed. Readers on this side of the Atlantic will be surprised at the pessimism which leads to the adoption of such radical surgical measures as Porro hysterectomy and extraperitoneal Caesarean technique for the potentially and actively infected cases. The segment technique has given such excellent results in these cases that few operators in this country would resort to more radical surgery. The same readers will be surprised to learn that chi-

nephritis is a common complication of pregnancy and will be critical of the statement that 26% of the cases of toxæmia at Johns Hopkins Hospital are found to be suffering from this disease. In discussing the oblique and transverse lie of the foetus the author emphasizes that this is usually a sign of disproportion between the foetus and pelvis yet rather surprisingly fails to warn of the possibility of placenta prævia.

This edition, in spite of paper restrictions is beautifully produced and lavishly illustrated.

PSYCHOTHERAPY IN GENERAL PRACTICE

Psychotherapy in General Medicine Reports of an Experimental Postgraduate Course. By Geddes Smith (Pp 38. Single copies 25 cents.) New York: The Commonwealth Fund, 41 East 57th Street. 1946. (London: Geoffrey Cumberlege, 2s.)

This booklet describes a fortnight's postgraduate course for general practitioners given in the University of Minnesota. The objects of the course were (1) To give the doctor a feeling of the dynamic qualities and the value of the doctor-patient relationship (2) to introduce him to the broad patterns of human motivation and to the common causes and backgrounds of emotional disturbance (3) to lead him to think in terms of the relation between emotional disturbance and illness (4) to teach him easily understandable methods of therapy so that he can treat a number of such patients (5) to give him some knowledge of more malignant conditions so that he may refer them to specialists. The first three of these objectives were attained adequately. The fourth could not of course be reached in a fortnight but it was thought that growing experience would gradually increase the doctor's ability to carry treatment further. The fifth was at least sufficiently achieved to ensure that the doctors would not commit serious errors.

Great keenness for and appreciation of the course was expressed and the instructors were encouraged by discovering that men in general practice could learn so much and so readily about ways of helping psychoneurotic patients. Inspired by this precedent it is hoped that much more will be done along these lines in this country.

OUTLINE OF SKIN DISEASES

Aids to Dermatology By R M B MacKenna M.D., F.R.C.P. Third edition (Pp 310 6s.) London: Baillière Tindall and Cox. 1946.

This useful little volume has changed a good deal since the last edition. It has lost the section on venereal disease which has now been segregated into a separate volume in the Students Aids Series written by T E Osmond. The dermatological part has undergone some revision and expansion and one or two points to which we took exception in the last edition have now been amended. But the book remains a handy size easily slipped into the pocket and not taking much room in the baggage of any practitioner who may be ordered off to one of the far-flung outposts of Empire. He will continue to find it informative and practical.

As a brigadier in the R.A.M.C. the author gained wide knowledge of the practical problems of dermatological therapeutics on a large scale during the recent war and it is no doubt greatly due to him that for the first time in military history the importance of skin disease was adequately recognized as a cause of disability in an army in the field apart from the rôle of cutaneous parasites in conveying serious and often fatal disease. In this little book he has been able to make some of the results of his experiences available to a wider public, and it is therefore additionally valuable. The chapter on diseases due to animal parasites which includes scabies and pediculosis, is particularly good. Unlike most books on dermatology there are very few illustrations—only about six figures—diagrams of the more important parasites. But this deficiency is easily understood for it would be quite impossible to illustrate it fully without destroying its handiness and (another factor of some importance) materially increasing the moderate price at which it is sold.

Jones A Finds the Body by HUGH McEVON (John Gifford 8s. 6d.) is a brisk story of murder in a military hospital during the war. The author is a doctor and as one might expect the book is happy free from both the scientific blunders and the sadistic grunting that have of recent years so often disfigured such works.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Essai de Mesure des Phénomènes Electriques Accompagnant la Pensée Emotive et l'Influence By N T Loressios and M Marchal (Pp 94 100 francs.) Paris: Librairie Maloine. 1946.

A study in electroencephalography from the point of view of relating particular wave patterns to the individuals from whom they were obtained.

Trabajos del Hospital del Rey Volume V. By Prof A M V de Simon et al (Pp 648 No price.) Madrid. 1946.

A collection of papers by various authors on a variety of medical and surgical conditions. In Spanish.

La Penicilina en Cirugía Maxilo-Facial By C M Squirru, M B Galea and H D Bianchi (Pp 158 No price.) Buenos Aires: Alfa. 1946.

Contains a general account of penicillin as well as a detailed description of its use in maxillo-facial surgery. Illustrated. In Spanish.

A Tiroide By H de Lacerda (Pp 151 No price.) São Paulo. 1946.

A monograph on the thyroid gland and its physio-pathology and disorders. Many illustrations. In Portuguese.

Cardiopatologia By A M Michelazzi (Pp 469 No price.) Turin: Rosenberg and Sellier. 1946.

A comprehensive account of the cardiovascular system in health and disease designed for medical practitioners and students. Includes diagrams, skiagrams, and electrocardiograms. In Italian.

Le Onde Ultra Corte Attraverso l'Encefalo By G C Giorgi (Pp 40 No price.) Turin: Minerva Medica S.A. 1946.

A monograph on the effects of ultra short waves on the brain with experimental evidence and a description of the apparatus used.

Minor Surgery By Cecil Fleming O.B.E., M.Ch. F.R.C.S. Twenty third edition (Pp 406 14s.) London: J and A Churchill. 1946.

The new edition of this well-known textbook has been considerably revised, particularly the sections on the treatment of wounds and fractures. Intended for house-surgeons, dressers, and junior practitioners.

Music in Medicine By Sidney Licht M.D. (Pp 132 \$3.) Boston: New England Conservatory of Music. 1946.

Treats of music as occupational therapy, background music, meal time music, psychiatry and music with detailed instructions for providing music as therapy and entertainment.

Klinische Elektrokardiographie By Max Holzmänn (Pp 624 50 Swiss francs.) Zurich: Fretz and Wasmuth. 1946.

A profusely illustrated work on electrocardiography.

Vitamine, Hormone, Fermente By R Abderhalden (Pp 250 14.50 Swiss francs.) Basle: Benno Schwabe. 1946.

A summarized account of the chemistry, physiology, therapeutic uses and available preparations of the vitamins, hormones and body ferments.

Ernährungsprobleme in Mangelzeiten By Prof A Fleisch (Pp 518 32 Swiss francs.) Basle: Benno Schwabe. 1947.

Problems of diet in time of famine with particular reference to the war years.

Dynamische Reaktionspathologie By Prof K von Neergaard (Pp 317 24 Swiss francs.) Basle: Benno Schwabe. 1946.

Develops a new biological approach to medicine.

Entstehung und Früherfassung des Portiokarzinoms By H Wespi (Pp 183 18 Swiss francs.) Basle: Benno Schwabe. 1946.

The origin and early diagnosis of carcinoma of the cervix uteri. Many photomicrographs.

Die Scheuermansche Krankheit By J E W Brocher (Pp 91 11 Swiss francs.) Basle: Benno Schwabe. 1946.

A monograph on Scheuerman's disease or adolescent kyphosis due to vertebral osteochondritis.

Psychoses et Nerroses By Prof H Baruk (Pp 136 No price.) Paris: Presses Universitaires de France. 1946.

An introduction to the fundamentals of psychiatry as the basis of therapeutic principles.

BRITISH MEDICAL JOURNAL

ENDOCRINES IN GYNAECOLOGY

Gynaecological endocrinology will be thirty years old this year. The beginning of this relatively young branch of medical science dates from Stockard and Papanicolaou's discovery in 1917 of the effect of the follicular liquor in producing oestrous changes in the vaginal mucosa. Thirty years is a short span in the life of any branch of medicine, and particularly that concerned with one of the most complex systems in the body, a system which is constantly changing and is susceptible to so many external and internal influences. It is long enough, however, for a sober appraisal of what has been accomplished and of what remains to be discovered.

No one is more competent to give such an appraisal than Mr Aleck Bourne. Elsewhere in this issue (p 79) readers will find his summing-up of the present position. It is not likely to encourage over-enthusiasm for endocrine treatment in gynaecology. The difficulties of such treatment are wisely emphasized. They depend on a variety of factors. Individual species' differences in the reaction to hormones even in species that are closely allied, have led to many errors and misconceptions when experiments carried out on animals have been interpreted in terms of human endocrinology. Not only are the conditions of the laboratory entirely different from those of clinical medicine, but each individual animal species, including man, appears to be unique in its endocrine make-up and thus in its reaction to hormones artificially administered. Adequate dosage is another problem and one which for the present has been solved only with regard to oestrogens. Other difficulties arise because the endocrine system is subject to continual rhythmic changes. Finally, the effect of the emotions further complicates changes in a system already subject to nervous and chemical influences, so that the effect of any known stimulus, emotional, nervous, or chemical, in the present state of knowledge is usually incalculable.

Bourne has introduced a new idea of great importance—that of endocrine receptors. So far the emphasis has been mainly on the stimulating agent—that is, on the hormone rather than on the organ receiving the stimulus. It seems strange that an idea so obvious should not have received closer attention in the great mass of work that has poured out in books and journals of all kinds in the last two decades. It appears that no one has ever inquired seriously into the reason why one organ or part of an organ, as for example the uterine endometrium, will react strongly to a hormonal stimulus that has little effect on other organs. But the matter is even more difficult because, continuing with the same example, the endometrium will react to progesterone only after it has been primed with oestrogen. Bourne's remarkable example of a case in which the vaginal mucosa

reacted normally to oestrogen whereas not the slightest evidence of reaction could be demonstrated in the uterus leads immediately to the conclusion that the uterus lacked something which was essential to its response. This conception of receptors within organs susceptible to hormonal influences though inevitable is a little disquieting. It reveals only too plainly the depths of our ignorance in a field where progress has often seemed so promising.

It is a relatively simple matter to summarize what is at present known about the hormones of the ovary and the anterior pituitary and their relations to the menstrual cycle and to pregnancy. Excellent descriptions with diagrammatic illustrations appear in textbooks of anatomy, physiology, endocrinology, and gynaecology. What is usually insufficiently emphasized is the delicate balance of the endocrine system as a whole and the dependence of one organ of internal secretion on another, or on all the others. Perhaps it is the anatomical remoteness of one gland from another, as of the pituitary from the ovary, that has led to this lack of appreciation of an all-important fact—that the endocrine system must be considered as being as closely integrated as, for example, the central nervous system.

The difficulties of the application of our as yet scanty knowledge are not overlooked by Bourne. Indeed he makes the comment that in face of all the difficulties success with hormone treatment should be deemed more remarkable than failure. In setting out the practical therapeutic value of sex hormones he comes to the conclusion that certain success can be forecast only in the suppression of lactation by oestrogens. Cure or relief is also to be expected in kraurosis vulvae and senile vaginitis, both probably a part of the same process of genital atrophy that occurs at or after the menopause. The value of endocrines in many other conditions for which they have so often been used in the past is rightly doubted. Uterine hypoplasia, often with primary or secondary amenorrhoea, can never be permanently cured by sex hormones. Artificial menstruation can be established by suitable dosage with oestrogens and progesterone, or sometimes with oestrogens alone, but if the trouble is of an organic nature permanent cure is impossible. Fortunately, in many cases amenorrhoea is a temporary affair due perhaps to an environmental change or to emotional disturbance, and regular menstruation returns often without or in spite of treatment.

In metropathia haemorrhagica the logical treatment is to give progesterone or testosterone, but often very large doses are needed and relapse occurs when treatment is stopped. In functional conditions such as spasmodic dysmenorrhoea, puberty menorrhagia, and menopausal disturbances the effect of treatment is variable and uncertain, probably partly on account of the large emotional element in many cases and partly because of our imperfect understanding of the nature of the disturbance. In many of these conditions, however, the judicious use of the correct hormone in the right dose may lead to improvement. Much has been written in recent years about habitual abortion, and doubt has been cast on the value of progesterone in these cases. Bourne favours treatment with progesterone, though he questions the value of injections on account of the inevitable fluctuation of the hormone level

when it is given by this means. He favours implantation of a crushed pellet of progesterone beneath the rectus muscle sheath, though he admits that his evidence in favour of this method of treatment is as yet inadequate.

This admirable summary of the present status of clinical endocrinology in gynaecology ends with suggestions for the future. The first essential is sound clinical research, and this raises the problem of how such research is to be accomplished. It must clearly go hand-in-hand with developments from animal experiments and from work on the biochemistry of sex hormones, including both the further study of known hormones and the exploration of possibilities of new synthetic substitutes for those naturally occurring. The discovery of the synthetic oestrogens, stilboestrol, hexoestrol, and dienoestrol, has been of great value in making it possible to reproduce the effect of naturally occurring hormones cheaply and easily, though in some ways it constitutes a real risk when these substances are prescribed by those not sufficiently conversant with their dangers and limitations, particularly, as is often the case, after inadequate investigation.

What, then, is needed for the future? Surely clinical research of the type envisaged is quite beyond the scope of the average gynaecological clinic, where cases needing endocrinological investigation and treatment are seen together with sterility cases and such purely surgical problems as prolapse and tumours of the pelvic organs. Investigation and treatment of disorders of the endocrines can be satisfactorily carried out only in large units equipped for all the elaborate investigations needed: biological and chemical hormone assays, histological examination of biopsy specimens, estimations of the basal metabolic rate, to mention only a few. A further advantage of the large unit is that it offers the opportunity, so often lacking in the past, of studying and treating a reasonably large series of cases of any one condition, with adequate controls. The work of the practical gynaecologist is often limited by the lack of facilities and by the pressure of more urgent surgical cases.

It may be argued that this will tend to lead to further specialization in gynaecology, a subject already highly specialized, but it is difficult to see how progress can be made from our present state of knowledge except along such lines. This is not to say that the work of the last thirty years has been wasted but rather that much of it has been misdirected, often through a misunderstanding of the magnitude of the problem. All the work so admirably summarized by Bourne must be regarded as a preliminary survey which has opened up great possibilities.

CANCER RESEARCH INTENSIFIED

The British Empire Cancer Campaign, at its annual meeting recently, rejoiced in a record income and in its ability to allocate £90,000 to various centres for cancer research in the year 1947. This is half as much again as the last allocation and a figure never before approached in the history of the Campaign, which now goes back for nearly a quarter of a century. To minds still bemused by wartime millions it may seem a modest sum for an attack on one

of the chief scourges of mankind, especially when it is apportioned among some twenty research centres. The chief value of the British Empire Cancer Campaign, however, is not that of a money-raising flag-day organization, appealing to the sympathies and apprehensiveness of the public; it is that of a central office for the distribution of resources according to a scientific assessment of claims and promises of performance. It works neither in a haphazard nor in a stereotyped way, and exercises the qualities of good generalship in sending reinforcements to the various theatres where the engagement seems closest and additional help most likely to make a breach in the enemy's line. The work done in the various laboratories, physics departments, clinics, operation theatres, and hospital wards is correlated and the workers are organized into a team. Through its Scientific Advisory Committee, of which Lord Horder is chairman, and to which the Royal Society and the Medical Research Council contribute half the membership, the whole field of cancer research—biochemical, biological, physical—is surveyed.

The rise of nuclear physics, the possibilities of which are foreseen only vaguely, dominates the picture presented in the Twenty-third Annual Report. Just before the war there was much discussion about the provision in this country of a cyclotron for the production of neutron beams for biological research. Later developments suggested something more ambitious, a national radiological institute for the investigation of the biological effects and therapeutic value of radiation. Towards the end of 1945 the Campaign called a conference at which the Royal Society, the Ministry of Health, and other bodies were represented. It had no sooner assembled than the announcement was made that the Government had set up a research committee on nuclear physics, and that three of its subcommittees were to deal with protection, tracer elements, and clinical aspects. The programme was therefore left in the hands of the Government, and, it is understood, is being actively pursued. Meanwhile some interesting work on tracers is being carried out at the cancer research department of St Bartholomew's Hospital and the department of pathology of St Thomas's Hospital. They have been experimenting respectively with radioactive sulphur and radioactive phosphorus for the study, in the one case, of the mode of action of anti-carcinogenic substances and in the other, of the mechanism of mitosis in transplantable rat sarcoma. Tracers allow a particular element to be traced through a long series of metabolic changes in the animal, and reveal the dynamic conditions prevailing within any type of cell or tissue. For instance, it is hoped to trace the dissemination of metastases from the Sheffield transplantable rat sarcoma (RD/3) by administering radioactive phosphorus (P^{32}) to the tumour-bearing animal so that it may become incorporated in the phosphorus-containing compounds of the tumour cells. Suspensions of these cells are then injected intracardially into rats, whose organs are later tested for radioactivity. Light may thus be thrown on why these tumours usually develop in certain organs such as the adrenals, liver, lungs and lymph glands, and leave others—e.g., brain, kidneys and spleen—unaffected. It is possible that radioactive stable isotopes may presently be suitable for the actual

treatment of cancer Work is also proceeding at many centres—the Mount Vernon, the Royal Cancer, and the Middlesex hospitals, and especially the Strangeways Research Laboratory at Cambridge—with the object of clarifying the factors which determine the response of cells to radiation and of making a more precise correlation between the response of normal or malignant tissue and the changes sustained by the cell components

The virus hypothesis of the aetiology of cancer has been vigorously pursued during the last few years by many workers, not in this country alone Following upon a report by Prof W E Gye on his visit to centres of virus research in the United States and Canada, a co-ordinated scheme for an intensification of research along these lines has been worked out by the Scientific Advisory Committee, and the Grand Council has been asked to allocate £25 000 to cover the cost of these investigations during the next two years Reports of work on viruses come from many centres, notably the Middlesex Hospital laboratories, where a new strain of Shope papilloma virus with promising properties has been obtained Another continuing piece of research is on chemical carcinogenesis, far too big a subject to be comprehended in one annual report The defect of annual reports is that some completed story, or at least some effective 'curtain,' is not attainable, for a subject like cancer research goes on from year to year One discovery which bids fair to throw more light on the history and behaviour of malignant growth is reported from the Chester Beatty Institute of the Royal Cancer Hospital under Prof E L Kennaway, who at the recent annual meeting of the campaign received the Garton prize and medal for his work in this field It has been ascertained that various aminostilbenes are an important class of carcinogenic agents, tumours being produced by them not only locally but at a distance as well From the same institute and also from the Middlesex Hospital laboratories and the Christie Hospital, Manchester, come accounts of work on urethanes (carbamic esters), again on experimental animal tumours Clinical trials of urethane were carried out in advanced and inoperable cancer in man, but they were mainly negative Nevertheless it follows from this work that while urethane, a mitotic poison, has little or no useful effect on malignant disease as a whole, it does bring about alterations in leukaemia similar to those obtained with x rays

Each year the report of the Campaign includes an analysis of cancer cases collected from London hospitals In 1946 nearly 1,500 cases of cancer of the rectum and anus were analysed Follow-up statistics in cancer are of great value, but they are open to many fallacies However, the committee in charge of the clinical investigation has had the criticism and help of Dr Percy Stocks, medical statistician to the General Register Office One feature brought out in this work is the influence of the hereditary factor in rectal cancer It is not conspicuous, though the figures are suggestive and seem to support the view that there is a hereditary factor relating cancer to a particular organ The most useful feature of these analyses concerns the effect of delay in treatment In 16 or 17% of these patients the symptoms were of more than six months standing when they first consulted a doctor

in 20% a rectal examination was not made until more than a month after the first consultation In more than half of those treated radically the disease was of more than six months' standing Radical operation was possible in only 32% of all cases, and of those only one-third were still in the early stages The five-year survival rate for all radical operations was 30%, and when estimated by actuarial methods the five-year expectation of life varied from 74 to 84% of the normal for early cases, down to 33% for the more advanced Some statistics are given from the Marie Curie Hospital concerning cancer of the body of the uterus a variety which has been considered rather resistant to radiation treatment, but, leaving out the cases in an advanced stage of the disease, the five-year survival rate at Marie Curie for the cases subjected to radiation is said to compare very favourably with that of surgery Another statistical report is from Leeds, concerning 300 cases of small skin cancers treated under carefully controlled dosage by single applications of superficial x-ray therapy The analysis showed disappearance of the lesions within two months of treatment, and only one case developed a small radionecrosis, which healed later This efficacy of the single application technique is difficult to reconcile with the present conceptions of radiobiology The Christie Hospital using a single exposure technique, states that it seems to produce an unusual incidence of late x-ray effects

The report of the Campaign, which again owes much to Mr J P Lockhart-Mummery's editorship, shows how slow, laborious, and intricate, how often contradictory, and how seldom attended by any spectacular or even conclusive results the work on cancer must be It is to be hoped that nobody will suppose that cancer research will now become solely a State responsibility Government encouragement is very welcome, but the initiative of the guerrilla soldier, the untrammelled pioneer, the free researcher, has been of no small advantage in this complicated strategy

INFLUENZA VACCINE

Since the discovery of influenza virus A by Andrewes, Smith, and Laidlaw in 1933 numerous attempts have been made to immunize human subjects by subcutaneous or intramuscular injection, or by intranasal insufflation of vaccines prepared from suspensions of infected murine lungs, chick embryos, or chick embryo tissue cultures These various preparations, in the active or inactive state, gave variable results in the hands of different investigators probably because of difference in antigenic potency, methods of inactivation, and other technical factors In 1941^{1 2 3} it was found that the allantoic fluid of infected chick embryos often had a high virus content Further improvements in technique resulted in the regular production of high-titre fluid, and this source of virus has been used almost exclusively of late for the production of vaccines The virus in the allantoic fluid has been concentrated by adsorption on to precipitates found in the fluid on the addition of protamine, alum, or calcium phosphate, by freezing and thawing, by adsorption on to and elution from fowl red blood corpuscles and by sedimentation of the virus by high-speed centrifugation

³ Nigg C Wilson D E and Crowley J H *Amer J Hyg* 1941 34 Sect B 138

Commission on Influenza *J Amer med Ass* 1944 124 982

A large-scale trial in the U.S.A. in 1943, of vaccine containing formalized influenza viruses A and B concentrated by adsorption on to and elution from fowl red blood cells indicated that suitable vaccines injected several weeks previous to or during the first few days of an epidemic might reduce the attack rate to one-fourth of that in control groups. In one centre, where the inoculations were carried out six to eight weeks before the onset of the epidemic, the vaccine was of little value. The effect of vaccine will depend on the antibody level of the serum of the individual and the amount of antigen injected. There is an optimum titre or threshold level of antibody in the serum (as measured by the chicken red-cell agglutination test), above which one may say the individual is probably immune, and below potentially susceptible. Henle and his colleagues found this titre to be 1:128. Henle noted that those with the lowest pre-vaccination level (1:16) showed also the lowest titre after vaccination. With increasingly higher pre-vaccination titres, the post-vaccination levels became markedly higher and the number of units of antibody formed likewise increased up to a certain maximum. Above this maximum there is usually no increase after vaccination.

Multiple injections of vaccine at weekly intervals do not improve the results obtained by a single administration, although several times as much vaccine may be used. Inhalation of vaccine in addition to a single intramuscular injection was without measurable effect, so far as serum antibody was concerned, in Henle's group.¹ The antibody response definitely improved, however, with increase in the dose of antigen although there was no difference between the antibody levels after six months in those who had received 1 ml. of protamine-concentrated virus vaccine and those who had received 3 ml. of allantoic fluid. The protection in either case would be sufficient for only one winter so far as influenza A is concerned. Henle has recently tested the possibility of improving immunization by addition to the vaccine of substances which would allow prolongation of the antigenic stimulus—a method which has been used by Freund with various bacterial antigens and by Friedewald² in the vaccination of experimental animals against influenza. The vaccine consisted of an emulsion of centrifugally concentrated virus in 'Falba' (a proprietary adsorption base said to be a mixture of beeswax, paraffin oils and oxysterols extracted from lanolin) and mineral oil in a ratio of 1:1:4. The dose was 0.3 ml. which contained 0.4 mg. of protein and was injected subcutaneously. There were no obvious reactions among the 80 recipients. Palpable nodules appeared in the subcutaneous tissues at the site of inoculation and persisted for 6 to 18 months. In two instances abscesses formed at the end of the second month. The immunization effect of the vaccine seemed to have been considerably enhanced especially against influenza B. Practically all subjects passed the threshold antibody level within two weeks and the titres remained high for at least 12 to 18 months. Such a vaccine may afford protection for at least two winters. An interesting point was that the antibody titres rose in spite of high antibody levels in the blood stream. It is suggested either that the antigen from the oil emulsion is protected against the antibodies or that cells involved in some phase of antibody production form part of the cellular response around the inoculum and therefore the antigen may not get into contact with the circulating antibody. Though this type of vaccine is not yet ready for general use in man it holds promise of providing in the future a more useful weapon than the vaccine now available for combating influenza epidemics.

MUSCLE LESIONS IN RHEUMATOID ARTHRITIS

It has long been recognized that the clinical characters of rheumatoid arthritis point to its being a general disease not confined to the joints, and Kent Spender described these features in considerable detail. Among other points he called attention to the fact that muscular atrophy is often an early symptom and may be in advance of, and out of all proportion to, any mischief in the nearest joints. Many authorities regarded this as evidence that the disease had its origin in the central nervous system, but no substantial evidence has been forthcoming to support this view.

Recently, pathological investigation has revealed local lesions in the peripheral nerves (Curtis and Pollard¹, Freund *et al.*²) and this has been followed by the demonstration of similar changes in the muscles themselves. Steiner, Freund, Liechentritt, and Maun³ examined portions of muscle tissue obtained by biopsy in 9 cases of rheumatoid arthritis and compared them with specimens from 196 controls; they found a condition in the cases of arthritis alone to which they have given the name 'nodular polymyositis'. The nodules were widely scattered throughout the muscular system without any relation to the joints, and consisted of inflammatory granulomatous tissue differing from the nodules found in other diseases of muscle. While the nodules were sometimes present without degeneration of the muscle fibres, early muscle-fibre degeneration was always combined with inflammatory lesions in the endomysium of the same fibres, and even in cases clinically 'burnt out' so far as the joints were concerned there was evidence of this inflammatory process being active in the muscles. The nodules were of the same type as those associated with the nerves and similar to the lesions in synovia and the subcutaneous nodules and entirely different from the nodules of fibrositis. The neuromuscular spindles were never involved, and the muscle lesions did not appear to be associated with the perineuritic lesions of the same character; the walls of adjacent arteries were invaded in a few instances.

Gibson, Kersley, and Desmarais⁴ have confirmed these findings and divide the lesions into two types differing in histological make-up and relation to the blood vessels; both descriptions are well illustrated. In one of their cases eosinophils were found in profusion, and it is suggested that this supports the theory of the aetiology of rheumatism involving anaphylactic hypersensitivity. Their controls, which included some cases of ankylosing spondylitis, were also negative, and a piece of muscle from a case of acute fibrositis showed no inflammatory cell reaction, though, as in the arthritis cases, the muscle fibres exhibited staining deficiency, loss of striation, and an increase in muscle nuclei. These authors suggest that the possibility that the arthritis may be secondary to the involvement of the soft tissues calls for further study. Both investigations furnish an important contribution to our knowledge of the pathology of rheumatoid arthritis.

COMMON COLD RESEARCH UNIT

The Common Cold Research Unit, set up by the Ministry of Health and the Medical Research Council, began work in May 1946 at the Harvard Hospital near Salisbury, on the most comprehensive investigation into the common cold yet undertaken in Britain. Volunteers have so far

¹ *Ann. intern. Med.*, 1940, 13, 2265.² *Amer. J. Path.* 1942, 18, 865.³ *ibid.*, 1946, 22, 103.⁴ *Ann. rheum. Dis.* 1946, 5, 131.

been largely drawn from among university students, but they have also included a number of industrial workers and V A D nurses. Volunteers spend ten days with the unit, and by the end of the year 129 had taken part. Many more volunteers are now required, particularly for the periods of mid-January to mid-March, mid-April to mid-June, and mid-October to mid-December. The aim, therefore, is to try to establish a national panel of volunteers. It is stressed that normal individuals of either sex between the ages of 18 and 40 are required. Cases of tuberculosis, chronic catarrh, asthma, hay fever, or sinusitis are obviously not suitable.

Those who are willing to enrol on this national panel and put their services at the disposal of the unit are asked to apply to the Medical Officer, Harvard Hospital, Coombe Road, Salisbury. They will then receive a special application form, full details of the investigation, and dates of forthcoming trials. Trials during the first half of this year for which volunteers are urgently wanted are Jan 29-Feb 8, Feb 12-Feb 22, Feb 26-Mar 8, Mar 12-22, Apr 23-May 3, and May 28-June 7. As volunteers live in pairs during the ten days they spend with the unit, applicants are advised to arrange, so far as possible, to enrol with a friend of the same sex so that both can remain together. Married couples can be accepted. Individual applicants can be accepted if there happens to be spare accommodation, or if they are prepared to share a hut with a partner of the same sex.

The present series of tests, under the general supervision of Dr C H Andrewes, of the National Institute of Medical Research, involves only the intranasal instillation of filtered nasal washings and other material believed to contain the cold virus on which work is proceeding at Hampstead.

PITFALLS OF ADOPTION LAW

Doctors, matrons of nursing homes, and midwives are often asked to help to get a child adopted, either because it is illegitimate or because the family are too poor to be able to keep it. They naturally desire to be as discreet as possible in order to preserve the patient's confidence, and are sometimes able to make private arrangements. It is not generally known that to do so is an offence against the law. In fact, this *Journal* once unwittingly overstepped the boundary by publishing an offer, sent us by a general practitioner, to adopt a child conforming to a given description. The President of the Medical Defence Union, Dr James Fenton, explained the position in a letter to the *Journal*, published on Aug 5, 1944 (p 194). He narrated that a member of the Union had attended a patient on the birth of her illegitimate child and had also attended a married woman who had been disappointed by the birth of a still-born child. The doctor brought the two women together with a view to the adoption of the child by the married woman. The welfare authority of his district pointed out that he was in breach of the Adoption of Children (Regulation) Act, 1939, which provides that, if arrangements are being made for a child under 9 years of age to be placed in the care and possession of a person who is not the child's parent or guardian or near relation, any third party participating in such arrangement must give seven days' notice to the welfare authority before the child is transferred. The Union was able to avert a prosecution of which the consequences might have been serious, for section 7, providing that any individual making arrangements for the adoption of a child under 16 must give notice in writing to the welfare authority, imposes a penalty of six months' imprisonment, a fine of £50, or both. The Act also forbids any body of persons which is not a registered adoption society or a local authority to make or cause to be made any

arrangements for the adoption of a child, on pain of a fine up to £200. This was the offence which the B M A would have been held to have committed if the offer of adoption published in the *Journal* had led to an agreement. It is also illegal to make arrangements for children who are British subjects to go abroad with a view to adoption. The General Secretary of the Church of England Moral Welfare Council, to whom we are indebted for the substance of these notes, points out that these prohibitions are imposed in the interests of children and suggests that doctors would be well advised to refer patients who wish to have children adopted to one of the registered adoption societies. These bodies make careful and confidential inquiries on behalf of all concerned and must supervise the welfare of the child until the adoption is legalized.

WESTMORELAND LODGE

Elsewhere in this issue (p 101) there appears an account of the new venture to which the Royal Medical Benevolent Fund stands committed. Westmoreland Lodge is to be a residence for some of the Fund's beneficiaries, and it will probably be ready for occupation by the early summer. Though until recently the project was known to but a few besides the Committee of Management of the Fund, it has been in contemplation for some time and has been approved by, for instance, the Charities Committee of the British Medical Association. The enterprise itself is evidence of an up-to-date outlook on the part of the Fund's executive, and this gives reasonable grounds for belief that any problems of administration which may arise will be solved. The profession at large may be safely assumed to be in cordial sympathy with this new development. A London surgeon said quite recently, on hearing of the scheme, that previously he had always had to take on trust the efficiency of the management of the Benevolent Fund, and now he was glad to find that his confidence was not misplaced. Dr Arthur Holdsworth Davis has created for himself an enduring monument. There may be other medical testators able to follow his example.

DELAYED PUBLICATION OF QUARTERLY JOURNALS

We much regret that there has been a delay in the publication of recent issues of the following quarterly journals published by the British Medical Association: *Archives of Disease in Childhood*, *Journal of Neurology, Neurosurgery and Psychiatry*, *British Journal of Industrial Medicine*, *Annals of the Rheumatic Diseases*, *British Heart Journal*.

This delay has been due to no fault of the editors of these journals, but to exceptional difficulties experienced by the printer. At no time since September, 1939, have there been so many obstacles in the path of a publisher. One of the chief causes in the delay of the publication of the above journals has been the inability of the paper mills to supply to the printer the paper on which they are printed. Every possible step is being taken to remedy the unfortunate situation that has arisen, and we can do no more than apologize to editors, authors, and subscribers for the most regrettable delay that has occurred from circumstances over which we have no control.

A special meeting of the Council of the British Medical Association was held on Wednesday, Jan 15. This meeting was called to receive the final plebiscite results, which appeared in the *Journal* of Jan 11 at p 64, to discuss correspondence between the Presidents of the three Royal Colleges and the Minister of Health on the National Health Service Act (p 66), and to consider the present position.

WESTMORELAND LODGE

BY

HENRY ROBINSON, M.D., D.L.

Chairman of the House Subcommittee

A few years ago the Committee of Management of the Royal Medical Benevolent Fund discussed a new project—a proposal to start a home for some of their beneficiaries especially for widows left alone and in distressed circumstances. For reasons valid at that time the idea could not be taken further until the late Dr. Arthur Holdsworth Davis bequeathed his own house with a substantial endowment fund to be utilized for precisely such a project. The Fund accepted the trust only to discover that Dr. Davis's wish was quite frustrated by the conditions set forth in the title deeds of his house whereby any such use of it was entirely prohibited. The house was thereupon sold for the Fund felt that the nearest attainment of his wishes open to them was to use the income of the whole legacy in grants for residential treatment in nursing homes, privates or convalescent homes for such of their beneficiaries as needed relief of that sort.

The progress of the war brought about so much greater a need for accommodation of the kind envisaged by Dr. Davis that three or four years ago the Fund set up a small subcommittee to explore the possibilities afresh. This resulted in a report accepted and endorsed by the Committee of Management of the Fund, that the establishment of a home was both practicable and highly desirable but that it would be wise to await the conclusion of the war before any active steps were taken to implement the policy. Eighteen months ago therefore the subcommittee set to work to find suitable premises conforming to several specifications suggested in their original report. Many houses both in London and elsewhere were inspected—work in which several members of the Ladies Guild gave most valuable help. After rejecting a great many properties the subcommittee decided to advise the purchase of Westmoreland Lodge, 27 Inner Park Road, Wimbledon Common, London S.W., as coming much closer to the ideals proposed in their report than any other which had been viewed. The Fund acted on this advice and purchased the freehold possession was obtained on Nov. 1, 1946. Architects had already been consulted as to the alterations that would be necessary; their report was presented by mid-November and approved with one or two minor amendments. It should be added that before the purchase was concluded permission had already been obtained from both the L.C.C. and the Borough Council for the intended new use of the premises. Assuming that the consent of the Borough Council to the alterations is given it is hoped that the opening of the house may take place in the early summer of 1947 at latest.

Westmoreland Lodge is a well built detached non-basement, mid-Victorian house in a very quiet almost semi-rural part of

Wimbledon but only about 300 yards from a bus stop on the Wimbledon-Putney route and therefore within easy reach of both centres for shopping and recreational facilities. It has a long but not very wide garden in fact the strip of land on which it stands is 140 yards in depth. The rooms are large—some of them so large that they can be subdivided into two—and the plans provide for the accommodation of twelve or more residents as well as for the Warden (Mrs. Ravner). Every resident will have her own bed sitting-room with either gas or electric cooking and warming facilities. It is hoped to install central heating. It is intended that the Warden and her staff will supply one substantial meal at midday, and that the residents will make their own arrangements for their other meals. There is a large room on the ground floor, big enough for a combined dining-room and common-room with a large glass-enclosed verandah outside for summer use. Extra bathrooms are among the contemplated modernizations, and each resident will have the use of a convenient washing-up

place. Two large refrigerators have already been obtained and will be available for the storage of their foodstuffs.

The furniture problem which promised to present great difficulties has been much eased by two pieces of good fortune. One is the highly valued gift of a houseful of furniture. The late Miss Wiltshire directed in her will that her trustee should give this to an approved charity—and the trustee was Mr. Underwood, honorary solicitor to the Fund. The other was the discovery by Mr. Pennefather, secretary to the Fund of a pre-war stock (therefore coupon-free) of small oak cupboards of a kind peculiarly suited for our purpose, they have metal tops on which gas-rings or electric cookers can safely be sited. Carpets may be more difficult to obtain a few have been purchased second hand (at high prices) and it is thought that some of the residents may have carpets of their own which they may wish to bring with them. Beds, of which none have yet been bought, bed linen, blankets, household linen, and table utensils residents are expected to provide for themselves, and difficulty is not apprehended on that score. Glassware, crockery and furniture for both the dining-room and some of the other rooms are included in the bequest already mentioned. About half the stair-carpet needed is in hand but more will have to be procured somehow. Curtains will certainly present a difficulty—those for the dining-room were obtained from the previous owner at pretty considerable expense. It will be realized, therefore, that there are several gaps in the equipment of the house—clocks are one such item not so far mentioned.

This brings me to the crux of the matter—finance. The purchase money £7,000 and the alterations which will cost a little under £3,000 are being provided out of the bequest of Dr. Holdsworth Davis but this of course reduces the income of the Fund because the money has hitherto been invested in interest-bearing stocks. The cost of upkeep will be considerable though no exact estimate of it is possible yet but the Committee of Management believe that whatever it may turn out to be the money will be well spent, and they hope that the profession as a whole will approve the action they have taken in the matter. Should the experiment turn out to be a success in course of time it may well be that further enterprises of a similar sort will be undertaken for example the provision of a hostel for infirm or even bedridden beneficiaries—for at present it is planned to accept at Westmoreland Lodge only candidates who can and will look after themselves keep their own rooms clean and cook their own teas and breakfasts.

The accounts of the house will be separately kept by the Royal Medical Benevolent Fund so that if any reader is disposed to support the project financially his or her donation or subscription can be credited to that account rather than to the General Fund if it be so desired. Mrs. M. W. Parry, during 1945 gave a donation of £300 in memory of her late husband Mr. R. H. Parry, F.R.C.S.E. to be set aside towards the establishment of the residential house. The Charities Committee of the British Medical Association has already signified

its approval by recommending to the Council of the Association a special allocation of £200 for Westmoreland Lodge. It is felt that there will be many other well-wishers within the ranks of the profession. Apart from money, the subcommittee will be most grateful for stair carpets and other amenities indicated in the foregoing description.

It has been decided—I think rightly—to associate the name of Arthur Holdsworth Davis with the plan, and a plaque will in due time be put up in the front hall to commemorate his munificence. Lastly, let me add that anyone who is interested and would like to visit the premises will be cordially welcomed, a telephone message to Mr Pennefather's office (1, Balliol House, Manor Fields, Putney, London SW 15 Putney 6128) is advisable so that a time can be fixed when either he or the Warden may be available. Inner Park Road is about a quarter of a mile from the *Green Man* at the top of Putney Hill along the road to Wimbledon. I myself will be glad to give any further explanation or information that is asked for, but application for admission should be made direct to Mr Pennefather.

THE NATIONAL HEALTH SERVICE ACT* SOME CONSTITUTIONAL AND MEDICAL ISSUES

BY

REGINALD T PAYNE, MS, MD, FRCS

"This is true Liberty when free born men
Having to advise the public may speak free,
Which he who can, and will deserve's high praise,
Who neither can nor will may hold his peace,
What can be juster in a State than this?"
Milton *Motto of Areopagitica*

There are two things that are uppermost in our minds at the present time. The first is that we are members of an ancient and a liberal profession, the second, that the National Health Service Act is now law. The immediate decision to be confirmed is whether or not we are to negotiate with the Minister of Health on regulations to be made under the Act. Such regulations would not alter the fundamental principles of the Act though they would affect its details. What is not generally recognized outside the profession is that although there has been a Negotiating Committee in being the Minister has hitherto refused negotiations.

Since the implications of the Act are far wider than their mere application to the medical profession, it is important to return to first principles if we are to define our individual attitude to the Act. I shall therefore approach the matter on two lines: first, from the constitutional aspect and, secondly, from the medical aspect. In other words, I shall try to answer two questions: How far is a Government Department to be trusted with the powers that the Act confers on the Minister? How far is a monopoly of medicine justified in a democracy? If we answer these questions as citizens who are members of a liberal profession, our duty and responsibility to the community will take us far away from personal or professional considerations, and certainly far away from mere expediency.

The catchwords of the age are organization and efficiency but we can achieve these at too great cost to freedom.

Some Constitutional Issues

The essential component parts of the Constitution are the Legislature, the Executive and the Judiciary. The Legislature makes the laws, the Executive carries them out and the Judiciary sees that justice is done. Owing to the increase in Parliamentary business, legislation is hurried and much less thoroughly debated than formerly, and it is also increasingly passed in skeleton form. This means a greatly lessened Parliamentary control over legislation itself, and little or no control over delegated legislation arising out of the Statutes. It also means that more and more of the work of filling in the framework of Acts is handed over to departmental officials. Few of the resulting regulations and orders are seen by members of the House of Commons and almost none are debated. Under

the National Health Service Act the majority of regulations will not require affirmative resolutions of the House. Delegated legislation is not only beyond effective Parliamentary control but it is also beyond the power of the Courts. The Executive department thus becomes Legislature, Executive and Judiciary. This short circuiting of the Judiciary has been put forward in some quarters as a means of forcing through schemes based on a particular social theory.

1 DELEGATED LEGISLATION

Acts of Parliament of a skeleton or enabling type have handed over to the Executive vast powers of making regulations. Such delegated legislation may be by Order in Council or by Departmental Regulations. This type of legislation has a long history, but as a method it has been increasingly used in recent years. During the 1914-18 war there was a flood of delegated legislation. It continued to a lesser extent between the two wars and was further greatly increased as emergency legislation during the recent war. Delegated legislation is constitutionally dangerous since it imposes a strain on the balance between legislative, executive and judicial activities. By concentrating function in the executive it diminishes the checks of the other two spheres. One of the most criticized features has been the power given to Ministers to override the provisions of a parent Act. Delegated legislation has been subjected to the most scathing criticism of judges, constitutional lawyers, and historians. In 1929 Lord Hewart in his book, *The New Despotism*, condemned the increase in the arbitrary executive powers and regarded the tendencies as sinister and despotic. Sir John Marriott in 1930, in *The Crisis of English Liberty*, a history of the Stuart Monarchy and the Puritan Revolution, considered the contemporary concentration of executive power a parallel danger to the despotic power of the Stuarts. Dr C. K. Allen, formerly Professor of Jurisprudence in the University of Oxford, recently expressed similar alarm in his book entitled *Law and Orders*. Further more whenever opportunities have arisen the Judges of the High Court have always shown themselves the strongest supporters of the citizens' rights against the arbitrary and despotic use of Ministerial powers. In 1929 the Donoughmore Committee was appointed to inquire into Ministerial powers, but most of the recommendations of its report passed into oblivion.

All parties are agreed in theory as to the dangers of delegated legislation, though all use the method during office. Many regulations have to be laid before the House as soon as may be, but in practice they may be locked away in cupboards in the library and, unless a Member is unusually curious, he will have no knowledge of them. Most of the regulations automatically become law after a short period of time. Others can be annulled by prayer. Regulations made as "Provisional Orders" on grounds of urgency escape all Parliamentary control. Recently a Select Committee was set up to examine statutory rules and orders. The unsatisfactory position can be appreciated by examining their third Special Report (Oct 29 1946). The Committee complain of the delay in publication and presentation to Parliament, of the tendency to make draft rules appear as if they were the final and valid instruments, of the printing of orders back to back, and of orders consisting of provisions purporting to give retrospective effect to the instrument where the parent statute confers no express authority. They also criticize five-tier legislation, which by cumulative delegations hands on powers to the great-grandchildren of the parent statute.

2 AURICULAR CONSULTATION OF JUDGES

In order to secure the independence of the Judiciary the Act of Settlement of 1701 provided that judges could not be removed except on the address of both Houses of Parliament. Previously, from time to time attempts had been made to tamper with the judges and undermine their independence. James I certainly did this and attempted to secure the judges' determination for the Crown. Sir Edward Coke, the Chief Justice, objected that "such particular auricular taking of opinions was not according to the custom of this realm." Charles I at the time of Ship Money similarly intervened to secure the judges for the Crown.

Lord Hewart, in his book, discusses in detail the most recent case where an attempt was made to establish a system whereby His Majesty's judges would be ordered and required to give

* Being the substance of some remarks made at a special Meeting of Fellows of the Royal College of Surgeons of England on Nov 29, 1946.

their opinions beforehand. This proposal was contained in the Rating and Valuation Bill 1928 and the department concerned was the Ministry of Health. The dangers of such a system are obvious and the detailed comments during the committee stage in the House of Lords gradually revealed the nature of the attack that was being made on the Constitution. Eventually the Minister of Health dropped the sinister clause.

3 QUASI JUDICIAL BODIES

Delegated legislation not only renders the Courts increasingly powerless but statutory tribunals of a quasi judicial nature are set up either semi-autonomously or within Government Departments to administer what I may call rough justice. Such tribunals exist in connexion with medicine, agriculture, rent, etc. and others have been appointed under the National Health Service Act. The essential characteristics of such tribunals are that their composition is not necessarily based wholly or partly on those trained in the law, witnesses are not necessarily on oath, the taking of evidence does not follow the usual court rules, the proceedings may be in camera, the Press are at times excluded and the right of appeal may be absent. Such tribunals are outside the main legal processes of the country. They thus fit in with delegated legislation and make executive rule much more complete. The dangers of these tribunals have been repeatedly stressed, and in an article in the *Spectator* of Oct. 6, 1944 Sir Henry Slesser pointed out that since the decisions of the tribunals are to be 'final and conclusive for all purposes' there has been a serious invasion of the rights of the individual.

4 GENERAL MEDICAL COUNCIL

The General Medical Council is a quasi judicial tribunal. Its penal activities have lately come under serious criticism for the reasons set out above. Attempts are now being made to secure that there shall be an appeal to the Courts from its decisions. It is therefore ironical that the Minister of Health should now secure to himself powers to prevent appeal to the Courts from the decisions of his tribunal. It is not generally realized that the General Medical Council is under the authority of the Privy Council. What will be the position of the Council's penal activities when all or most of the Council are State servants?

5 THE NATIONAL HEALTH SERVICE ACT TRIBUNAL

This Tribunal is a Government tribunal. The relevant words of the Act are as follows:

The Tribunal on receiving representations from an Executive Council shall and in every other case may inquire into the case and if they are of the opinion that the continued inclusion of the said person in any list to which the representations relate would be prejudicial to the efficiency of the said services shall direct that his name be removed from that list and may also if they think fit direct that his name be removed from or not be included in any corresponding list kept by any other Executive Council under this Part of this Act.

The decision of the Minister's disciplinary tribunal is final. There is no appeal from this quasi-judicial body. The offending doctor may have been justifiably dismissed or he may have infringed some minor Ministerial regulation or he may not have carried out treatment in accordance with some Ministry of Health circular or his political or private views may not coincide with those in authority and the Minister decides to terminate his employment. From this there is no redress and no appeal. The evils of the penal system of the General Medical Council will be perpetuated and aggravated by this Government tribunal.

6 RENDERING THE COURTS POWERLESS

With the mounting volume of delegated legislation and the increase in judicial powers granted to Executive Departments the citizen finds it increasingly difficult to secure redress in the Courts. The various quasi judicial bodies also limit appeal to the Courts. The Executive thus becomes prosecutor, judge and jury in its own case and the citizen is rendered helpless. Finally, time after time Executive Departments not content with their existing powers have acted in the most arbitrary fashion and taken the law into their own hands. Fortunately the Courts have proved the citizens' stoutest defenders in these cases of *illegality*. The seriousness of the situation has been and still is being stressed by the judges and by constitutional writers.

7 THE CROWN PROCEEDINGS BILL

The individual is at a grave disadvantage in claims against the Crown. An action which would be successful against another citizen may fail when the Crown is litigant. Owing to the unfairness of the position a committee was appointed in 1921 to inquire into the matter and reported in 1927. Subsequently a draft of the Crown Proceedings Bill was put forward with the object of giving equality to the individual in claims against the Crown. This Bill has had the support of all political parties of the judges and of the Bar. Nevertheless there have been all sorts of delays and the Bill has never been proceeded with. The rapid extension of nationalization and the mounting numbers of Crown servants in the community make it a matter of elementary justice to secure that the Crown has no special privileges as an employer in the eyes of the law.

Recent legal decisions stress the even greater urgency of the matter. Lord Justice Scott in summing up an action in which the Crown was involved—*Royston v. Cavey* (*The Times Law Report* Nov. 12 1946)—is reported as follows:

With the complexity of modern business carried on by Government Departments and the great increase in commercial concerns owned by the Government, it was a crying evil that legislation to remedy the position should not be passed by Parliament. He wished to express his opinion as strongly as possible that it would be a crying wrong if the necessary legislation was not introduced at an early date.

But in so important a matter affecting the citizen's legal rights the Government can hold out no hope of early legislation. Thus nationalization robs the citizen of legal remedies.

8 CERTIFICATION

A consideration of certification is included here, as the subject has been made a political one. Any doctor who has had experience of practice knows the problems presented by certification. We are faced with human material and not abstract propositions and in issuing certificates the doctor does his utmost to serve his calling justly. In the latter part of the debate on the National Health Service Bill in the House of Lords the Lord Chancellor spoke as follows: 'No one could have been as I have been, Minister of National Insurance without realizing that the success or failure of all our schemes depends in a very large measure on our getting satisfactory certification. If we are going to have lax—still more, dishonest—certification then all our schemes are going to break down on that rock. Certification is thus the crux of the problem. The Government is going to control the doctor because if the doctor were not controlled he might be 'lax or dishonest' or worse still he might treat his patients with kindness and humanity. The doctor is to be coerced because as a humanist he is not to be trusted. And who defines satisfactory certification?' The Minister of Health and his officials. Perhaps when a production drive is in progress the Minister of Labour may arrange a further tightening up of certification. The Lord Chancellor's statement is a damning admission of the Government's intention.

In a letter to the *Journal* of Dec. 4 1943, I commented on the use of *agents provocateurs* in attempts to trap a medical practitioner into giving certificates. In the case in question three police spies admitted they had acted on instructions from the Criminal Investigation Department, that they had been instructed to give false information and to feign sickness to the doctor and that they had also been told what to say. All these facts were admitted by the legal representative of the Director of Public Prosecutions. The charges against the doctor were dismissed and costs awarded against the prosecution. The magistrates' comments on this case left no doubt as to the importance he attached to honesty in the relation between patient and doctor. If suspicion in connexion with certification is to be the underlying principle governing the attitude of the authorities then it will be a sad day for Medicine. The fact that a few men are lax or dishonest is an insufficient reason for putting the profession in chains or for justifying the employment of spies from Government Departments to see how we are doing our work.

9 THE CLOSED SHOP

The significance of the recent Willesden episode has not been lost upon the profession. If a local authority can

instructions ordering all its employees, including its nurses and doctors, to join their appropriate trade unions or professional organizations, it leaves little to the imagination to realize the coercive powers in the hands of the Minister of Health. Since the recent repeal of the Trades Disputes Act, 1927, more and more local authorities have made union membership a condition of employment.

The first condition of employment is the production of a union ticket. The individual trade union is affiliated to the Trades Union Congress, and a contribution to the political funds of the Labour Party is automatically secured unless the individual member contracts out, and contracting out may be a matter of grave difficulty in certain communities.

Doctors therefore have not been slow to realize the implications of the Willesden episode. We will not be a party to any proceedings which make our activities part of any 'closed shop' organization. An organization where union membership is a primary condition of employment and that union is linked to one political party rapidly approaches the one-party State. This is not merely a question of which political party is involved. So long as we remain a free and liberal profession we will have no dealings of this type.

10 THE MINISTRY OF HEALTH

The record of the Ministry of Health in constitutional matters is such that if aware of the facts, no citizen would willingly concede any increase in powers to the Ministry, and no doctor would willingly hand over either the sick public or the medical profession to the sole charge of such a Department. What is the evidence that has led constitutional writers to criticize the activities of the Ministry of Health beyond all other Ministries?

A It has constantly used the method of skeleton legislation leaving the substance of Acts to be determined by departmental regulations.

B It was one of the Departments most responsible for the huge increase in delegated legislation between the two wars.

C It has constantly used the procedure of 'Provisional Rules' to enforce its decision on grounds of urgency. Such regulations become valid immediately they are made, and may remain in force for years though unconfirmed by Parliament. More than half the regulations made by the Ministry of Health under the Local Government Act of 1929 were of this type.

D It has used in its legislation the so-called Henry VIII clause, which gives an executive authority 'power to amend the present Act, or (usually) any other Act in order to bring the present Act into 'full operation'. By extension it enables the Minister if any difficulty arises, in bringing an Act into operation, to 'remove the difficulty' by Order. This obnoxious and arbitrary type of legislation was used under the National Health Insurance Act 1911, the Rating and Valuation Bill 1925 and the Local Government Act 1929.

E The Ministry of Health was the Government Department which most recently attempted to tamper with the independence of the Judiciary. This occurred in connexion with the notorious Clause 4 of the Rating and Valuation Bill, 1928. This clause would have allowed the Minister to submit doubtful points of law to the Courts and, by being armed with anticipatory opinions, would have denied justice to litigants. The clause was attacked in the House of Lords as a most sinister attempt at Executive encroachment on the independence of the Judiciary.

F The Ministry of Health is already choked with quasi-judicial functions. These include the hearing of disputes in connexion with National Health Insurance, Old Age Pensions, Blind Persons, etc. The even less than quasi-judicial ministerial local inquiries have come to be regarded as mere farces.

G The Tribunal of the Ministry of Health under the National Health Service Act will be an additional quasi-judicial function. It will not be a legal tribunal, it will merely be a tribunal for the exercise of the Minister's administrative discretion.

H For the foregoing reasons the Ministry of Health has been the Executive Department where there has been the greatest concentration and confusion of legislative, executive and judicial functions. As its powers have increased, so has it been able more and more to prevent appeal to the Courts.

One of the most recent examples of the activities of this Ministry is described in *The Times Law Report* of Jan. 26, 1944, in an action—Minister of Health v. Bellotti and Another. The following is from *The Times* summary of the Master of the Rolls' judgment.

He could not leave the case without saying this. Where persons were to be ejected from premises which they had lawfully occupied, the general expectation would be that recourse would be had to the Courts rather than to the high-handed method of ejection by force. That was particularly applicable to a Government Department, which one would expect to act with some sense of dignity.

'But the Ministry concerned here having failed to secure obedience to its rules, instead of coming to the Courts proceeded with the help of four porters, to try to drag the respondents from the flats. That having failed the next step appeared to have been to withdraw the respondents' meal tickets, and in fact to endeavour to starve these people out.'

He did not think that that particular incident was one which those responsible for it would look back on with any sense of self-congratulation, and it was to be hoped that that type of action would not be regarded as a precedent. He would say no more except that he did not like departing from the strict path when delivering judgment, to administer rebukes, but he did it because it was very relevant on the question of costs.

This is the Ministry which is to be entrusted with entire charge of the sick public and full control of the medical profession.

Some Medical Issues

The National Health Service creates a monopoly of Medicine in regard to hospital and consulting work and makes general practitioners subject to a measure of State control hitherto unknown. It is an Act for the better control of doctors and their patients.

1 *The Patient*—Under the Act the patient can only be seen at hospital by a consultant who is a State employee. Even if the patient goes to the part-time consultant privately the latter will still be a State servant. There can be no really independent opinion for the patient, and independent opinions in connexion with his patient's welfare. Hitherto the conscientious Medicine are needed and will always be needed. All consultants see cases where it is essential to the patient's best interest to have an opinion absolutely independent of any local authority, trade union, or Government Department. The general practitioner is also placed under a grave disability in that a doctor has been able to advise his patient to go to this or that hospital or to this or that consultant, and he has chosen the hospital or consultant in relation to the special problems presented by his patient. That freedom of the general practitioner to do his best for the patient will now be hedged by Ministerial regulations or directives. In future the doctor will have to send his patient to the appropriate officer, at the appropriate hospital in the appropriate region. The State controls the relationship between the patient and the consultant, and the general practitioner must give up his position as counsellor and adviser.

2 *The Consultant*—The hospitals are in the hands of the Minister and are controlled by the Minister. The hospital staffs are restricted to those in the Service. The Minister controls all the beds and has refused to negotiate on this. The consultant therefore has the choice of joining the Service or being liquidated. Mr. Bevan does not conscript or direct the consultant but he produces a 'Coercion Act' which says 'Join or be destroyed'. The voluntary hospitals have not contested the Act in the way that might have been expected, and they seem to have forgotten the living principles which founded them.

3 *Patient and Consultant*—Under the Act all hospitals become State hospitals, and the definition of a 'hospital' is so wide as to include any institution for the reception of the sick. If the consultant is to have hospital beds he must therefore have them within the State service. Mr. Bevan's recent sop to consultants should deceive no one. The independence of the honorary consultant within the State service must be short-lived, and the logic of the situation must force all consultants into the salaried service. The patient will then have no choice of seeing a consultant outside the service since independent consulting work can be carried on only from independent institutions. The elimination of free association of doctors and patients is a doctrinaire restriction of the freedom of the public and the independence of the doctors.

4 *The Medical Student*—How will the Act affect the type of students? Hitherto Medicine has attracted a variety of types. That variety has been determined by the variety of careers that Medicine offered. In the future that variety must

be sacrificed and will be limited to men and women who are content to work within the framework of a rigid Service. There will be less scope for individual initiative, and less for purely personal considerations. Variety must be sacrificed to uniformity. The ambitious doctor of the future will be the administrative climber and not the scientist, humanist or artist. The only serious criticism of the medical student type has been that owing to the cost of the training it has been impossible for youths from the poorest homes to take up Medicine. This is certainly true. But it is also true that although men from humble homes have made excellent doctors, the poorest home is not a real background for the future doctor. But in the future the student is to be State-aided, State-conditioned and rendered servile, docile and mobile.

5 *The Royal College of Surgeons of England and Other Medical Corporations*—What will be the position of the Council of the Royal College of Surgeons in ten years' time? By that time half the Council will be civil servants in all but name, and the other half will be Government pensioners. What will have happened to the much-prized independence and prestige of the College then? It will no longer be the Royal College of Surgeons; it will be the Royal College of Surgical Serfs.

What will be true of the Royal College of Surgeons will be true of every medical corporation. The Fellows forming the respective Councils are invariably consultants and as such will be Government employees who must carry out the instructions and wishes of their master, the Minister of Health. The Minister will not be their immediate master, but he is in a position to exercise his authority. He can declare that the corporations' examinations are no longer recognized by the State, or that the higher examinations are no longer necessary in a world of 'graded-specialists'. And by so doing he can at a stroke of the pen destroy both prestige and income. And why should not the Minister do these things by Departmental regulation? There is certainly nothing to prevent him if we acquiesce in working his Act. The destruction of the independence of the medical corporations means their destruction as expert medical bodies.

6 *The Central Health Services Council*—This Council which is to advise the Minister of Health looks formidable enough on paper. Six members are *ex officio* and the other thirty-five are appointed by the Minister. But will it be either formidable or disinterested when most of its members are State servants or State pensioners and the Minister of Health is their employer? The Presidents of the Royal College of Surgeons of England, of the Royal College of Physicians, London, and of the Royal College of Obstetricians and Gynaecologists may now be impressive figures, but in ten years' time their respective Colleges may have lost all their prestige and most of their power, so that their respective Presidents' real capacity to offer independent and expert advice to the Minister will not be worth a fig. It will be more important to keep on the right side of the Minister and his officials than to offer independent advice or criticism. It will be more important to know your Minister than to know your medicine. It is not without significance that the Minister is enabled to suppress either in whole or in part the publishing of the Councils' Annual Report to Parliament if the public interest should demand it. Who is to decide the matter of public interest? The public or Parliament? Neither, the Minister. Such a proviso at the centre of the Health Service hands it over at once to the possibilities of obscurantism, dishonesty and jobbery.

7 *The Scientist*—What will be the position of the doctor as a scientist under the Act? Will every publication of every medical man employed in the Service have to pass the official scrutiny of the Minister of Health's officials? Will the right to publish be taken from the doctor and be dependent on the whim of some medical official? Will the real test no longer be scientific or clinical interest or advance, but the furtherance of official policy or a desire to hoodwink the public? Will the publications department of the Ministry have an eye on possible repercussions on the Treasury? Will the doctors' reports be doctored before being published, and will the obedient official doctor get preference over the less acquiescent one?

These are not merely theoretical matters. In the early part of the recent war I was engaged in carrying out some research

in connexion with peptic ulceration. At only one hospital was I asked to suppress a piece of evidence. That occurred at a hospital directly under a Government Department. In that hospital I asked one of the senior medical officers if there was any statistical evidence that disease X had any connexion with peptic ulceration. I was told that there was definite statistical evidence, but that under no circumstances must I mention the fact or claims might arise and the Treasury would object. Scientific medical facts are suppressed because their publication might be inconvenient. Think of the endless possibilities under the Health Service Act for the suppression of scientific facts in the interests of official policy or Treasury economy. But doctors in this country are humanists first and scientists second, and the humanist may prove a harder nut to crack than the scientist.

Conclusion

The National Health Service Act is symptomatic. It takes away the personal responsibility of patients and doctors and substitutes the coercive activities of the Minister of Health and his officials. In view of the constitutional and medical implications of the Act, what evidence is there that the doctor should lift a finger to assist in implementing its provisions? What evidence is there that would justify our handing our patients and the medical profession into the keeping of such a despotic Executive Department as the Ministry of Health with its unhealthy constitutional record? History does not support the view that the State can be regarded as a "kind nanny" where the interests of citizens are concerned and Medicine has duties and obligations to the community which are not compatible with mere Departmental status. What evidence is there that the health services will even be improved? The fundamental feature of this Bill is to transfer all real power to the Minister. If the Bill is operated no patient or doctor will ever feel safe from interference by some Ministerial edict or regulation and no independent institution connected with Medicine will feel safe from interference, expropriation or dissolution. The Minister's spies will be everywhere and suspicion and intrigue will rule. Power corrupts and absolute power corrupts absolutely. Lord Acton's words are as true to-day as when they were written. The medical profession is still a free and independent one and it is our duty to assert our democratic rights and those of the community at large against the encroachments of the Executive.

I owe allegiance to no political party. As a liberal I am alarmed at the destruction of individual and personal freedom and the substitution of the coercive power of the State. The present constitutional crisis of liberty is comparable to that of the seventeenth century. Then it was the attempt of the King to become a tyrannical power and overrule Parliament complicated by attempts at religious uniformity. Now it is the weakening of Parliamentary control and the concentration of power in the hands of the Executive.

The community is not coextensive with the State. The democratic community is built up of all the various individuals with differing needs, hopes and capacities. The modern State is a central organization which attempts to establish a central philosophy for its citizens. So that when Mr Morrison talks of the design for corporate living informed by a conscious philosophy (*The Times* Dec 17 1945) we know that he and his friends are prescribing their philosophy for the community. Such philosophy uses men as means and not ends. It is the philosophy of infallibility in Church, State or party. It obliterates the individual, the spontaneous and the native forces of democracy and substitutes central direction and uniformity.

No Government or political party in this country dare attempt State uniformity in either religion or education. Religious toleration of minorities was established two hundred years ago. Education has repeatedly proved a thorny problem for statesmen and administrators and the recent Education Act did not impose a State monopoly. But the doctors alas are easy prey. They are good-natured and overworked and their work in a social service has been exploited by all political parties. Meanwhile voices are being raised that other callings must be nationalized and made free for all. State-sponsored free-law-for-all may have some advantages, but it has grave dangers.

In the face of the spiritual and political tyranny of to day we shall serve the community best by standing by our essential freedoms Do not sell that birthright for a mess of pottage Do not exchange that freedom for pay and a pension Do not give up the right of association either as members of the public or as doctors Do not become gagged Government functionaries with minds in cold storage Health organization and even health itself can be bought at too great a cost to freedom And what evidence is there that health will be gained? Freedom and liberty are conditions of health and conditions which allow of constant change and constant adaptation Coercion and the centralization of power mean sudden change and then stagnation The analogy of 1912 is utterly false At that time Parliament was alive, the Executive had not become a tyranny, and the State was not regimenting its citizens in every sphere of life

We are members of a free and liberal profession I want that freedom to continue as one of the freedoms of a democratic community As healers of the sick, we shall continue to give our best if free from State coercion

INCREASE IN CAPITATION FEE

The following statement on the current capitation fee has been issued from the Ministry of Health A report of the special meeting held on Jan 8 by the Insurance Acts Committee to consider the Minister of Health's proposal to raise the capitation fee appears on p 5 of the Supplement this week

An agreement has now been reached between the Minister of Health and the Insurance Acts Committee of the BMA on the application of the Spens Report to the current capitation fee under the existing National Health Insurance scheme Mr Bevan has proposed that the present capitation fee of 12s 6d should be increased to 15s 6d, with effect from Jan 1 1946, and that there should in addition be an increase in the special payments made to rural practitioners

In making this offer the Minister has made it clear that remuneration under the new National Health Service will be a matter for negotiation with the medical profession Some of the factors on which the 15s 6d is based will, in his view, have a bearing on the negotiations for the remuneration in the new Service, which, it is agreed, will be on a higher level than the remuneration now settled for health insurance The Insurance Acts Committee of the BMA, in accepting the offer have stated that they have done so without prejudice to the assessment of remuneration in any future service

RELEASE FROM THE FORCES

The Central Medical War Committee is informed that medical officers in the following age-service groups are being released during the first three months of 1947

	January	February	March
Royal Navy	57	58	59
Army			
(a) General duty officers	54	55	56
(b) Specialists	42	43	44
Royal Air Force	54-56	—	57

Reports of Societies

BRITISH ORTHOPAEDIC ASSOCIATION

The Annual Meeting of the British Orthopaedic Association held in London on Oct 18 and 19, under the presidency of Mr GEORGE PERKINS opened with a discussion on Fractures of the Os Calcis

Mr N W ROBERTS and Mr W SAYLE CREER had each followed up some scores of cases over several years and had independently reached similar conclusions concerning compression fractures involving the subastragaloid (subtalar) joint, namely, that an incapacity period of about a year in cases treated by reduction and immobilization was approximately halved in cases treated by early movement More than three quarters of the patients returned ultimately to full work in their old occupations, and the proportion was not materially influenced by the method of treatment adopted Mr W GISSANE, nevertheless, considered reduction important, and showed a film illustrating its performance and maintenance with a sagittal os calcis pin Mr K H PRIDIE demonstrated some patients, including a policeman who showed extremely good function following excision of the os calcis—an operation to be reserved for the most severely affected

In his presidential address, Rest versus Activity in the Treatment of a Fracture, Mr GEORGE PERKINS confined his remarks to fractures not directly involving joints Activity was of importance in preserving the extensibility of muscle thereby preventing stiffness If both fragments in a fracture bore muscles, these would look after immobilization and the sole function of the limited splinting necessary was the preservation of alignment Failing this condition (as in fractures of the femoral neck, medial malleolus, and scaphoid), splinting was necessary not merely for alignment but also for immobilization Such splinting must be prolonged, uninterrupted rigid and extensive, consequently it impaired function, and internal fixation was often preferable

Prof E SORREL presented a paper on the treatment of tuberculous arthritis, in which the results of some usual and unusual extra-articular arthrodeses were illustrated He strongly advocated arthrodesis as a final stage of treatment, deferred however, until active disease was at an end

Prof H J SEDDON showed a film of preliminary work carried out with Dr A E BARCLAY on the cineradiography of joint movements Mr K I NISSEN gave a comprehensive account of Morton's metatarsalgia with a clinical and pathological description of 13 cases in which he had excised the fibromatous thickening first described by L O Betts of Adelaide He had carried out a follow-up of three years and more Mr I LAWSON DICK discussed the late results of iliac bone transplantation and Mr L GILLIS showed a film on amputations near the elbow joint

At the General Meeting Mr S A S MALKIN was elected president for 1948-9 and Mr F G Allan and Mr E A Nicoll were elected to the Executive Committee

SOCIAL SERVICE AND THE HEALTH ACT

The British Federation of Social Workers in collaboration with the British Council for Rehabilitation arranged an all day conference of social workers on Dec 7 at the Royal College of Nursing to discuss the new situation created by the National Health Service Act Mr ALEXANDER FARQUHARSON presided

Alderman C W KEY Parliamentary Secretary to the Ministry of Health, in a brief exposition of the Act, said that it was comparatively easy to put into the words of a statute the steps it was desired to take in the curative field, but prevention and rehabilitation were more indefinite and therefore more difficult to express in black and white Yet this indefiniteness might be an advantage, for if the functions of social workers closely set out in the Act and then in a few years' time new development came forward it would be unfortunate because they were bound by the Act, they were free from using their experience and skill He went on to say that the fact that the Minister would own the hospitals would

not mean a stereotyped service, from one point of view the Minister's ownership was unimportant for he had no intention of administering them and there would be a chain of administrative agencies down to the committee of the individual hospital. One function at present exercised by many hospital almoners—that of assessing a patient's ability to pay—would cease altogether, but many more tasks would open out including liaison between the almoner's own hospital and the other hospitals and health services of the region.

One of the principal functions of local authorities under the Act would be the provision of health centres. There would be plenty of room for variation and experiment in this direction. Emphasis would be laid on the social and educational functions of these centres. In the family doctor service there was a place though a less definite and extensive one, for the social workers.

We want the doctor to do a lot more than just cure the immediate ailments of his patients. I hope it is true to say that the good general practitioner recognizes more and more the need for the appraisal of the whole social background of his patient and the need for help beyond his own scope in getting things straightened out. He added that the National Health Service Act was only one part of the Government's programme for the reconstruction of social services. With it would go fresh legislation to break up the old Poor Law and to establish welfare services for children and the aged.

Lady CYNTHIA COLVILLE took up a point made by Mr Key that it would be the duty of the health visitor to go into the home. Hitherto she thought, the success of the health visitor had resided in the permissive character of her visits. If now she was to have a right to go into the homes it might undermine the value of her work. Mr KEY replied that the duty was one laid on the local authority to provide a health visitor service, it would still be at the option of any person to accept the service or not. Miss MACDONALD said that the almoner would now for the first time be free to exercise her true function as a social worker. Patients had hitherto looked on the almoner only as the lady who collects the HSA vouchers.

The Social Worker and Industrial Health

Dr H F CHARD opened the second session with a description of the various branches of industrial medicine. A personal letter conveying the doctor's recommendations was the best medium for reports on patients who were returned from the hospital to the factory.

Mr C E A BEDWELL said that if in theory the family practitioner was the backbone of the Medical Service it was as well to make him so in fact. The factory medical officer must be subordinate to the family doctor. Documents from the hospital should be sent not to the factory medical officer directly but via the family doctor, whose responsibility it was to provide such information as was necessary for the factory.

DEVON AND EXETER MEDICO CHIRURGICAL SOCIETY

Obliteration of Cavities in Pulmonary Tuberculosis

On Nov 14 the medical and surgical aspects of collapse therapy were discussed by Dr C J FULLER and Mr ALAN GAIRDNER.

Dr Fuller said that lesions in the lung were so commonly apical because inhaled bacteria gravitated into sub apical branches of the upper bronchi. The thorax might be regarded as a semi rigid cylinder with the diaphragm acting as a piston. The object of collapse therapy in pulmonary tuberculosis was to rest the lung without putting the patient to bed. A subject with a totally or partially collapsed lung was often able to go on doing sedentary work, and except in advanced cases temporary artificial pneumothorax was a method of choice for each.

Mr Gairdner pointed out that though some tuberculous cavities closed spontaneously others did not especially if filled with pus. Surgical intervention brought about concentric collapse of the cavity but a free pleura was necessary so that relaxation could be complete in all directions. If there were adhesions to be cut thoracoscopy was called for, if there were cavities low down in the lung phrenic avulsion might be necessary. Thoracoplasty might be more widely employed in

afebrile 'good chronics' with a unilateral lesion and cavitation, in which some attempt at healing had occurred, and in unilateral cases which were afebrile and going downhill, especially if pus-filled cavities were present.

Chemotherapy

On Dec 5 Sir LIONEL WHITBY discussed the present position of the sulphonamides in relation to antibiotics. It was not always easy to choose the most appropriate sulphonamide in any given case. The original prontosil, discovered in 1935 was merely sulphanilamide in combination with an inactive red dye and was found to be effective against most of the Gram positive pyogenic organisms except the pneumococci and staphylococci. At least 5000 compounds had been synthesized subsequently in an attempt to improve upon the original substance. Unless it was to be used against the pneumococcus or staphylococcus sulphanilamide was as effective and cheap as any other compound. Sulphathiazole had to be given four-hourly, sulphadiazine six-hourly and sulphamerazine eight-hourly if an effective blood concentration was to be maintained. Sulphathiazole in macrocrystalline form was useful for local application.

All these drugs acted by inhibiting the multiplication of bacteria, probably because they were mistaken for *p*-amino benzoic acid the natural 'food' of pyogenic organisms. They should be given as early as possible in an infection and used prophylactically whenever possible. It must be remembered that pus contained *p* aminobenzoic acid so that once pus formed sulphonamides were useless. Sulphonamides acted quickly and if given in proper concentration and without result within from seven to ten days their use should be abandoned. It was of no use changing to another sulphonamide. Oral administration was the method of choice. When applied locally these drugs were absorbed into the blood stream.

Complications of chemotherapy were vomiting, cyanosis, leucopenia, haemolytic anaemia, haematuria, anuria and skin sensitization. As an increasing proportion of the population received treatment with sulphonamides sensitization was becoming commoner. Drug fever and skin rashes might occur together. Rashes followed local application, which should never be continued for longer than five days at a time. Intractable dermatitis and photosensitivity were serious complications.

Penicillin had replaced the sulphonamides in the treatment of many, but not all diseases. It was useless for example against such Gram-negative organisms as *E coli*. Sulphonamides therefore still had a place in the treatment of urinary tract infections where they were concentrated in the kidney about 50 times and so need not be given in large doses but could be used for long periods. Sulphasuxidine was probably the most effective drug at present against Sonne dysentery. Penicillin powder was taking the place of sulphonamides for local application, but mixed powders were of doubtful efficacy. Penicillin by mouth was useless. It was easily destroyed by acids, alkalis, synthetic rubber or by contamination with airborne organisms and it was very hygroscopic and thus easily contaminated and rendered impotent. Penicillin was suitable for intramuscular and intrathecal administration, but if used intravenously was apt to cause local venous thrombosis.

Streptomycin, the latest of the antibiotics, was highly active against Gram-negative organisms and it also appeared to act against the tubercle bacillus, especially in acute forms of the infection. In contrast to penicillin it produced toxic symptoms with overdosage and was probably not the last word in the treatment of tuberculosis. Streptomycin acted against *Procyaneus* and *Protens* but was less effective against the typhoid and *Salmonella* groups.

At a meeting of the Chelsea Clinical Society, held on Dec 10 with the president Dr Ronald Jarman, in the chair, there was a discussion on 'Plastics in Surgery and Medicine' opened by Dr Stanley Leader, followed by Mr Robert Cutler, who dealt with the dental applications of this material. Many specimens and quite original uses of plastics were shown with emphasis on the need for correct selection of the type for any given purpose. Other speakers included Mr N Eckhoff, Dr Desmond MacManus, Dr Niall MacManus and Dr Langdon Lloyd, to whom Dr Leader replied.

Correspondence

The Presidents and Mr Bevan

SIR—It is doubtful whether much notice should be taken of Press opinion on the result of the plebiscite, for much of it has been unsound and contrary opinions have clearly cancelled themselves out. It is much more important for our profession to know that we can expect little help from any of the political parties. Our voting strength is negligible, and politicians will neglect our interests to obtain credit either for starting or for not opposing the National Health Service.

The present position is one of great interest for the Government have adopted the method of imposing a 'Diktat' upon key members of the community, which has quite naturally provoked a strong protest. It reflects great credit upon our profession that political considerations have found no expression in our reaction to the new Act. Our purpose has surely been to obtain the best possible medical service for the individual members of the State. Refusal to negotiate was the only course open to us, and I hope that the medical profession will stand firm and wait until the next move is made by the Government.

The Act contains so many bad features that I doubt whether it would operate successfully even if it had the full co-operation of the medical profession. We must avoid, above all things, being placed in the difficult strategic position when we as a profession would be blamed for defects in an Act for which we are not responsible.

The correspondence between the Presidents of the three Royal Colleges and the Ministry of Health has caused dismay. However good their intentions their action can only split the profession, for some of us will feel that we owe loyalty to the Royal Colleges, while others who believe in democracy will stand by the machinery of the British Medical Association—I am etc.

London W 1

WILFRED SHAW

National Health Service Act

SIR—In conversation with doctors and laymen certain points in relation to the National Health Service Act have become obvious. A frequently expressed question is 'Why do the doctors not produce an alternative?' To that the only reply is that the Medical Planning Commission's alternative, although inadequate, was produced and has (despite *The Times* of Jan 6, 1947) been largely ignored. Had we taken the stand that to produce a good national medical service the present Act is unnecessary, since financial support is all that is required to develop the medical services of this country to an adequate degree, we should have had a very much greater public and parliamentary support for the control of the purse-strings is sufficient.

Another question is 'Why do you not concentrate on your strongest point, that the medical profession is to be the only body in the community to be deprived of the right of legal appeal?' This requires no amplification.

The last point—and here we have failed lamentably in presenting our case—is that we did not in the 'Principles' emphasize sufficiently the fact that our aim is the provision of an adequate medical service available to all who need it irrespective of financial capacity. This last it is not too late to remedy—I am etc.

Southsea Hants

NIGEL CRIDLAND

SIR—At a meeting at B M A House early in 1946 the subject of discussion being the National Health Service Bill, we were advised by Dr Hill to put our case before the public. I ventured to ask how it was proposed this should be done and received a reply which at the time did not seem altogether satisfactory but having myself no satisfactory suggestion to offer I did not pursue the subject.

In the end pamphlets were printed by the thousand and lay, I fear for the most part unread on the waiting-room tables. Some letters were written to a far from friendly Press, and in the end the Bill became an Act without any effective opposition. A proportion of the Press is definitely hostile to the views of the majority of the profession, ascertained by the

recent plebiscite the rest is lukewarm in its sympathy. A fortnight ago I heard denounced as failing in Christianity those doctors who decided not to co-operate in working the National Health Service Act.

Obviously our methods of approaching the public are at fault, and the difficulties facing us now the Bill has become an Act are infinitely greater. How is the curtain between the medical profession and the public to be raised? It is of little use meeting together and urging one another to do this or that. Unless we get the support of the public we can do little. Surely what are required are meetings open to the public, to whom we can explain our case, prepared to receive some hard knocks, and even to hear some unpleasant home truths. This is not an original idea, for at the beginning of the campaign some far seeing Divisions put the plan into practice, but it was not widely adopted.

The public, having the Act explained to it with all its implications, may yet be in favour of the Act but the small amount of space devoted to the Bill by some of our leading daily papers run by, first of all, business men and only secondly idealists shows that these men felt their public were not interested and were content to remain ignorant. It is this apathy and ignorance we must strive to dispel if we hope to bring our campaign to a successful conclusion—I am etc.,

London W 8

HAROLD H SANGUINETTI

SIR—Owing to the great courtesy shown by you in sending me the *BMJ* during the year (in spite of my not having paid my subscriptions since 1941, owing to having been interned as a prisoner in Siam, and still having no assets to pay them with) I have been able to visualize the present conditions and anxiety regarding the future of every member of your Association in the United Kingdom (is it really united?). Though I have lived for the past forty two years in Siam I feel that perhaps for that very reason I possibly may be able to see the whole wood and not confine my vision to an odd tree or two, as appears to be the case with the majority of correspondents who write letters to the *BMJ* regarding the immediate future of medical practitioners in the United Kingdom. I note with some concern that the majority chiefly exhibit concern regarding the practitioners, and much less so regarding the practice of medicine, or those that they practise upon and I cannot help but feel that these last two are mentioned in their letters as secondaries rather than as primaries, as they should be.

Certainly every opinion expressed in those letters is right—so are the different opinions expressed by the Government or the Opposition—but right only to the extent that they are all given in good faith. Otherwise those opinions are simply the result of the personal emotional bias or sentiment of those who give those opinions, and, as I can find no common denominator anywhere among them, to me it seems to be analogous to trying to multiply a donkey by five apples in order to visualize an elephant. If you do not somehow find that common denominator there will be another war—and this time between doctor and doctor, with politicians and the public taking sides, hence at war also—with the result that everybody guilty and innocent, will again suffer the pains of war and none of the pleasures of victory. Yet President Truman says 'The world is sick of war'.

I therefore beg to suggest a common denominator. As demand creates supply, practitioners of the science and art of healing simply exist to supply a demand from the public and could not exist but for that demand. The Government—every Government and every Opposition—exists for identically the same reason, and when the public does not like a Government it turns it out and would do the same with every medical man if it wanted to. For the past three hundred years the United Kingdom has had Governments increasingly selected and elected by the people, and I believe the average age of each successive Government is somewhere about five years. I have never yet read that during that three hundred years apart from individual changes, the public have ever yet threatened to dispense with doctors as a whole or even a large section of them or ever objected to the treatment they received from the medical fraternity as a whole, while the same certainly cannot be said of either politicians or the Governments they control. Therefore one must conclude that the public—the man in the street—is a fool, or that he strongly approves of the medical fraternity of the United Kingdom for the simple

DIPHTHERIA — WHOOPING COUGH

ONE immunological course

The success of the campaign for diphtheria im-
munisation focuses attention upon the gravity of
the figures relating to whooping cough

For this reason and for the efficient convenience
of doctor parent and child Glaxo Laboratories
have introduced a new preparation in which the
antigens of diphtheria and whooping cough are
combined. Named 'Diphtheria Prophylactic
A P T plus Pertussis Vaccine (Alum Precipitated)',
this preparation enables simultaneous
prophylaxis against both diseases to be con-
densed into a course of three injections (0.5 cc,
0.5 cc, and 1.0 cc) at monthly intervals. Each
cc contains in equal proportions, the customary
Diphtheria A P T (at least Lf 25) and 20,000
million H pertussis alum-precipitated.

reason that as a fraternity—a brotherhood—it has ever bowed to public opinion and supplied what was demanded from it while Governments and politicians have not done so

As the public—the people of the United Kingdom as a whole—is master both of the Government and the brotherhood of practitioners of the science and art of healing, surely here is your common denominator. Taking polling results, one sees a very large proportion of the public do not take the trouble to vote for a new Government, because they are much more interested in to-morrow's dinner than in to-morrow's Government unless one affects the other. I have never yet heard of any single individual who was not keenly interested in who should attend him if he were sick, quite irrespective of to-morrow's dinner so why not leave it to the public—the public as a whole—to judge which side is right?

In this last war it was not the Governments that fought for the freedom of the British Empire but every man, woman and child, who were determined to retain the freedom they had held for a thousand years against Normans Spaniards French Germans, Italians, and Japanese. They won because they were free and their opponents were not.

Cannot my brethren trust such a people to decide fairly regarding this issue, this war the result of which affects most intimately the freedom of every man, woman and child in the United Kingdom? Yes! I think they can and will. A country, a people which starting quite unprepared and which for two long years alone held the fort of national freedom surely is capable of organizing a scheme to follow out the above suggestions, treating the matter not as a war between my brothers and a temporary Government but as a struggle of my brothers to preserve their collective freedom. If such a scheme cannot be found, then it is a sure sign that England is no longer free except in name but the feudal serf of an authoritarian Government which it cannot control, which arrogates to itself the right to remain free to do as it likes, and at the same time to deprive the public of its inherited freedom—I am etc,

S am

M CARTHEW

SIR—Admittedly we as a profession advocated a National Health Service to include dependants of insured persons and provide laboratory facilities for all. The Act which has been passed is a travesty of these principles and while it may not benefit the practitioners it certainly will be to the detriment of the patient, who will incidentally be paying through the nose for it.

Its main aim, in my opinion, is to control certification, and the general practitioner will only be responsible to his immediate superior and have little interest in the patient at all. It is my earnest desire that the profession as a whole will reject this totalitarian method of turning a once noble profession into a Civil Service—I am etc,

East Kilbride

J McLAREN

Conditions of Service under the Act

SIR—I am strongly of the opinion that immediate steps should be taken to publish a statement both in the medical and lay Press and also if thought advisable to convey it to the Minister to the effect that the medical profession would almost certainly be prepared to work the National Health Service as set out under the Act if the following questions of principle were conceded

- (1) The right of appeal to the courts against dismissal from the Service
- (2) The right of all boards, councils and committees set up under the Act to appoint and remove their own chairmen
- (3) The removal of anything in the Act which would tend
 - (i) to restrict the relationship between the general practitioner and his patient
 - (ii) to bring the doctor under the direct control of the Minister of Health of the day—namely the clauses in the Act which (a) make the doctor the tenant instead of the owner of his practice (b) restrict his right to practise where he pleases (the distribution of doctors could easily be safeguarded by regulations or orders, and by arrangement with local executive committees)
- (4) The avoidance of any form of basic salary as a means of payment of general practitioners. This would make the doctors' remuneration at least in part dependent on the

Minister's assessment of his worth instead of on the number of patients who choose him and would inevitably create divided loyalties which, among other things might have the effect of restricting the doctor's freedom of action in giving certificates. This state of affairs would obviously militate against the interests of the patients—I am etc

London W 1

DORIS M ODLUM

The Plebiscite

SIR—There are two remarks in the statement by the Chairman of Council on the plebiscite as published in the *Journal* of Dec 21, 1946 (p 957), which do not appear to me to be justified. In the first place Dr Dain states that of the doctors mainly concerned—i.e. the general practitioners—64% had voted against negotiating. I must protest against the statement that general practitioners are those mainly concerned, and would point out that of those who voted only 45% were in categories 2 or 3—i.e. general practitioners or their assistants. If it is the view of the Council that the votes of the remaining 55% were to be considered of less value than those of the general practitioners, a statement to this effect should have been made before the voting took place.

The second statement to which exception can be taken is

The young doctors effectively support the majority against negotiation. There is no question of age overweighting the decision. Reference to the table of results shows that the percentage against negotiating in the four age groups gets progressively larger from the younger to the older groups—namely 47, 50, 56, and 60 respectively. From this it would appear that it is the older members who are responsible for the decision that the committee should not negotiate.

It is to be hoped that the Representative Meeting will bear these facts in mind when considering the recommendation of the Council, who, I understood Dr Dain to say at a meeting held at Hertford, are themselves by no means unanimous as to whether the profession should negotiate or not—I am etc

Welwyn

A P FORD

SIR—Dr H B O Cardew (Jan 4 p 29) asks us to accept his view that the Labour Party, who believe that nationalization is the cure for all evils, and who actually received fewer votes than the other two parties together who take the opposite point of view, has a clear mandate from the country to pass the Health Act. If we do this we must still more recognize the fact that the B.M.A. has a clear mandate from the whole profession by 56% to 44% that no further negotiations on this present Act should take place. Does Dr Cardew really believe that by turning the doctors into Civil Servants and by creating a large army of lay Civil Servants to work the Act the public will get a better service or can it be that it is not only those who are opposed to the Health Act who may have self-interests?—I am, etc,

Camberley

LESLIE HARTLEY

SIR—The plebiscite is stated to be a decision as to the principles of the profession. On a matter of principle all members have an equal voice, just as all are equally subject to accepted ethical principles and serve equally on ethical committees and the G.M.C. whether consultant, G.P., or whole-time salaried M.O. On Dec 12 there was known to be a majority of 3,496 out of 56,671 against negotiation. Dr Dain said (*Journal* Dec 21 1946) The B.M.A. is a democratic body and the Council has no mandate to negotiate.

This majority derived very largely from the 4,959 majority of the 17,841 G.P.s. 21,021 other civilian doctors had a majority for negotiation. The votes of 8,600 Service doctors are omitted. Dr Dain said (*Journal* Dec 21 1946) quoting the recommendation that the Council had decided to lay before the Special Meeting of the Representative Body on Jan 28.

Because of the divergence between the principles of the profession and the provisions of the National Health Service Act the Committee is unable to enter into negotiations. There was this known majority against negotiations on Dec 12 of 3,496. There was a majority against negotiation among general practitioners qualified more than 15 years of 3,597. Dr Dain said 'There is no question of age overweighting the decision.'

By provisions under another Act patients will be paying contributions, but not for medical care after the appointed day since the B.M.A. says 'No.' Hospitals will be expected

to reject Government aid. Chemists will have no Government-franked prescriptions. Doctors will have no Government pay. Patients, hospitals, chemists, and doctors will have less money. The standard of medical care will inevitably fall nor has the B.M.A. been able so far to persuade the Divisions to agree to any scheme of organization of what care will be available. Dr Hill said: 'The doctors will be loyal to their calling and to their patients, to whom as always they owe their first duty. And all this because of a majority of 3,496 out of 56,671. There must be an Amending Act, a precedent for every trade union that disagrees with any future Act. The Commons, the Lords, the Royal Assent go for nothing. This present Act does not exist—because of 3,496 out of 56,671—I am, etc.,

Hove

WILLIAM BOURNE

SIR—As one of the doctors in the Services who did not have an opportunity of voting 'Yes' or 'No' in the recent ballot I would like to draw attention to an aspect of the result to which insufficient attention appears to have been given—and that is the fact that only 40% of the profession actually voted against any renewal of discussions with the Government. No less than 35% voted in favour of negotiating while as many as 25% either did not or could not vote at all.

The point to be observed therefore is that the profession appears to be fairly evenly divided in opinion upon the matter and therefore it is doubtful whether the B.M.A. could count on the support of any substantial majority of the profession in seeking at this juncture to break off negotiations upon an Act which has already become the law of the land.

The Presidents of the Colleges, in their constructive letter to the Minister, dated Jan. 2, have outlined the main objections felt by doctors to the Act, and the Minister has now made a conciliatory reply in which he has expressed a willingness to negotiate freely within the framework of the Act and to endeavour to meet any views of the profession which do not conflict with the principles of the Act.

There can surely be little justification, in view of these circumstances, for now persisting in refusal to negotiate.

The Act is now law, but the details of its shaping still depend largely upon the results of free and constructive discussion between the Government and the doctors. It is surely in our own interest and, even more important in the interest of the nation, for the medical profession at this stage to approach the problem in a spirit of constructive co-operation, free if possible from political bickering, and to do all in its power while there is yet time, to advise the Minister on all matters which require clarification, elaboration or amendment within the framework of the Act—I am, etc.,

London NW 3

A B COOK

The Press and the Doctors

SIR—You write in your leading article entitled 'A Moral Issue' (Dec 28, 1946 p 993) that the medical profession as a result of the plebiscite has had a bad Press. It may be pertinent to point out that some journals have descended to actual misrepresentation of facts in their desire to belittle and traduce the conclusions to be drawn from the answers to the plebiscite. For example *The Times* in its issue of Jan. 6 prints on its front page a statement that 'the clumsy attempt to enforce a closed shop on municipal, medical and nursing staff undoubtedly influenced the doctors voting in the recent ballot'. The forms asking doctors to vote were issued in the week ending Nov. 16 and recipients were urged to reply as soon as possible. The 'clumsy attempt' was made on Nov. 29, by which date it would be a safe bet to assume that nine-tenths of replies had been made.

The *News Chronicle* in its issue of Dec. 14 reported hopefully a 'break-away movement from the B.M.A.' in certain bodies which it described as 'medical unions,' 'the biggest being the Medical Practitioners Union and the Confederation of Health Service Employees'. It went on to say, 'at present there are about 10,000 doctors in 15 or 16 unions' and it urged that these medical unions should 'get together and act as one'. It is reported that the Socialist Medical Association which 'is a political organization affiliated to the Labour Party,' expressed the confident conviction that 'fewer than 10,000 doctors will refuse to co-operate with Mr. Bevan'.

On Dec. 16 I addressed a letter to the *News Chronicle* pointing out that there is only one body—the Medical Practitioners Union—which is recognized both by medical practitioners and by the T.U.C. as a medical trade union, its present membership I stated on the authority of the general secretary to be approximately 4,000, as compared with 7,000 before the war, while the B.M.A. during the same period has grown from 40,000 to 54,000. I asked for evidence supporting the statement that 'there are about 10,000 doctors in 15 or 16 unions'. In a covering note to the editor I said I did not expect him to publish my letter but I hoped he might wish to correct statements which were clearly not in accordance with facts. Needless to say no notice was taken of my communication—I am, etc.

House of Commons

E GRAHAM LITTLE

Five Impossible Clauses

SIR—Mr. Bevan's reply to the Presidents of the Colleges leaves the situation quite unchanged. There are five clauses incorporated in the Health Service Act which it is impossible to remove by negotiation, since Mr. Bevan is only ready to negotiate within the principles of the Act. These are:

- (1) The basic salary
- (2) The refusal to allow an appeal from the Ministers' decision in cases of dismissal
- (3) The direction of doctors. Under the Act no doctor can settle in any district without the permission of some local or county organization
- (4) The refusal to allow the buying and selling of practices. This is fundamental, for eventually the State will be the owner of every practice in the country. This means a State monopoly of medical practice and the complete subjugation of it to the State with all that that implies
- (5) The penal clauses, which are outrageous to any free community

All these things are beyond negotiation now that the Bill has become law. Before, however, we say 'No' finally, is it not possible for the B.M.A. to elect a committee to discuss these vital clauses with the Minister with a view to discovering the possibility of removing these fundamentally objectionable clauses by means of an amending Bill? The rest of the Act is more or less workable, but these five clauses make it impossible for the majority of us to accept the Act. On the result of that discussion we should be in a position in which we could say 'Yes' or 'No' beyond question—I am, etc.

Histon Cambs

A E MOORE

Allergic Reactions to Penicillin

SIR—Allergic reactions to penicillin were reviewed by Dr A. I. Suchocki (Dec. 21, 1946 p 928). He recorded forty-seven cases and divided them into four classes: (a) allergic hyalrthrosis, (b) urticaria, (c) simulating serum sickness, (d) anaphylactic-shock like syndrome. All these reactions followed intramuscular injections of penicillin. The following record is of interest in that the father developed hyalrthrosis and the son developed urticaria after sucking penicillin lozenges, and both proved very sensitive to a penicillin skin test.

CASE RECORD

On Dec. 13, 1946, I was called to a boy aged four and a half years who had pain on swallowing, pyrexia, and swollen discharging tonsils. I prescribed penicillin lozenges to be sucked during alternate hours and small doses of aspirin, phenacetin, and Dover powder. On the first day he seemed to enjoy the lozenges, on the second day he had to be coaxed to take them, and in the evening developed swollen lips and said his 'tummy tickled'. When I saw him on the third day his tonsillitis was considerably improved but he had oedematous lips and large urticarial weals on abdomen, thighs, and upper arms. He had refused penicillin that morning. No more penicillin was given and the next day his urticaria disappeared, to reappear for a short while in the evening.

On Dec. 29 I rubbed some penicillin ointment (500 units in 1 g into an area of approximately four square inches (25 sq cm) on the upper arm. The skin immediately turned crimson and stung so for twelve hours, the patch being visible for twenty-four hours. Plain petroleum jelly rubbed into a similar area produced no coloration.

On the second visit to the boy I was asked to see the father who complained of a tickling throat and a feeling of incipient

head cold I advised him to suck some of the penicillin lozenges. Two days later his left knee was swollen, with fluid in and around the joint. It was tender but not red, and his temperature was normal. The penicillin lozenges were continued, and by the next day his right knee was mildly affected in the same way, and hydrarthrosis of the joints of the fingers prevented full flexion. The penicillin was stopped and within twenty-four hours the joints appeared normal. A skin test showed a sensitivity equal to that of his son.

This record shows once more how indiscriminate use of penicillin can produce startling results. It also points out the benefit of knowing about a patient's sensitivity to penicillin, so that an attempt may be made to desensitize him in preparation for a possible future sudden need for penicillin—I am, etc.,

Leeds

R A MURRAY SCOTT

SIR—Dr A I Suchecki's article on the above subject (Dec 21, 1946, p 938) prompts me to write of a recent case which showed somewhat unusual features. On Oct 14, 1946, a male patient of mine was admitted to hospital because of an acute septic infection of an old gunshot wound above the right ankle. For five days he had sodium penicillin parenterally in repeated doses amounting to 100,000 units each 24 hours, and there was a rapid improvement both generally and locally. Penicillin was continued as a local treatment and improvement was maintained until on Nov 22 he developed a mild urticaria on the neck and shoulders and two days later a generalized angioneurotic oedema, which gradually subsided under "benadryl."

The interesting features seem to be (a) the late reaction—five weeks after cessation of parenteral treatment—and (b) the development of severe sensitization during local application—I am, etc.,

Cambridge

J N TURNBULL

Curare

SIR—The use of curare in the production of relaxation has been hailed by many anaesthetists and surgeons as a milestone in anaesthesia. The comments of the nursing profession are, however, very different. I have made inquiries of half a dozen ward sisters, and without exception they condemn the use of curare on three grounds: first, that patients are more frequently in a condition of shock when they return to the ward. This is probably due to insufficient anaesthesia. Secondly, that marked respiratory depression is usually present, which requires the unremitting attention of a nurse for a long period of time. Thirdly, that paralytic ileus frequently complicates the recovery of the patient. This condition may of course come on after any variety of anaesthetic, but the impression is gaining ground that it occurs much more frequently after the use of curare for an abdominal operation. One of my surgical colleagues has received a letter (which I have permission to quote) from the matron of a nursing home in which she asks whether she is justified in restraining anaesthetists from using curare in her home owing to the many cases of ileus that have occurred and the inability of her nursing staff to cope with them without the presence of a resident medical officer.

Insufficient attention is often paid to the point of view of the nurse in the assessment of a new drug. Too little time is spent by the modern anaesthetist in the ward, watching the post-operative course of his patient. Curare is an extremely valuable addition to the armamentarium of the anaesthetist, but it is not the perfect anaesthetic drug—for which we are still seeking—I am, etc.,

London W 1

MASSEY DAWKINS

"Lissive" Action of Curares

SIR—The recent article on *d*-tubocurarine chloride by Kellgren *et al* (Dec 14, 1946 p 898) is not quite correct where it implies that we attributed the selective rigidity-removing ('lissive') action of some curares to a sedative effect upon the central nervous system.

We were unable to establish the source of the 'lissive' action of curare in canine tetany or in man. We found it to be the property of some samples only, and those samples could not be identified geographically. One of us subsequently found the same property (in respect of canine tetany only) in the non-quaternary alkaloidal fractions of certain *Strychnos* and other

plants (1937), and noted that its presence was accompanied by a mixture of curariform and strychnine-like actions. It thus seems possible that the 'lissive' action of some curares is due to a combination of two antagonistic effects—one centrally excitant, the other peripherally depressant. If this is so, the fact may ultimately be capable of therapeutic exploitation. We are, etc.,

Acroparaesthesia and its Treatment

SIR—Some time ago Dr F M R Walshe discussed this syndrome in the *Journal* (Nov 3 1945, p 596) and also described it in the fourth edition of his *Diseases of the Nervous System*. This syndrome is found chiefly in women but recently I have found it also in men. It consists of weakness and stiffness in the forearm, especially when starting their work in the morning, and dropping things from the affected hand which feels clumsy. In addition there are symptoms of a neuralgic character—numbness, and pins and needles in the fingers and hand. There is always marked tenderness of the extensor muscles in the forearm. Walshe prescribed rest as the only effective treatment. In severe cases he advocated a week in bed propped up during the day, with the arms in slings and taken out only for feeding, etc.

For several months now, following the work of Good (*Minor Medicine* p 169) and Kelly (*Ann rheum Dis* 1945-6, 5, 1 69) I have treated several of these cases with excellent results. The treatment consists of injecting 0.5% procaine into tender spots found in the extensor mass at the level of the neck of the radius. The needle is inserted into the muscle and its point is then used as a probe to find the tender spots. When the exact spot is located by the needle point there is no doubt about it, for the patient, however stoical, will be unable to suppress a wince. Inject 0.5 ml, then probe for other spots watching the patient's face and inject again.

After treatment, when the anaesthetic effect has worn off, the pain may be worse for a day or two. The patient should be warned. Great relief follows. If this is not complete further injections may be given in a week's time. At this second examination the injected spots will no longer be tender but others will be found in much the same area. It is seldom that the injection treatment has to be repeated more than twice—I am, etc.

A P MAGONET

Endogenous Depression in General Practice

SIR—I was interested in the article on this subject by Dr C A H Watts (Jan 4, p 11), particularly in his emphasizing that most of these cases can be treated outside a mental hospital with much better results, with this I am in entire agreement and it is the goal and aim of most medical men. Among the doctors in mental hospitals we have some who are most distinguished and of the highest integrity, but there are others who are unfortunately incompetent for this type of work or who are indifferent, under whom the patient gets better in spite of them and not because of them. Very much good is done in some mental hospitals, but in others there is much that could be improved and there is a tremendous drainage of the nation's money, medical man-power and nursing staff, who take away with one hand what they unsuccessfully and feebly attempt to give with the other. When the patient comes out of hospital he finds attributed to him qualities so peculiar and so amusing that the whole position would be farcical if it were not so deadly dangerous and tragic.

I would most earnestly appeal, Sir, for the complete reorganization of conditions in some mental hospitals which it is public knowledge, are far from good and for breaking completely the archaic laws and decaying bonds which loosely bind the whole structure. They perpetuate the very conditions which they are impotent to cure. It is a system which needs rapid clarification from the shroud of obscurity which surrounds it in an abyss of futility and waste.

I was interested to read also in the same issue (p 33) the remarks of Dr L Sheldon, who states that no fewer than

four cases—two of carcinoma of the stomach, one of gastric ulcer, one of advanced pulmonary tuberculosis—were erroneously diagnosed as cases of anxiety neurosis within six months, to his knowledge alone. I would like to ask Dr Sheldon what would have happened if by a chain of circumstances these patients had unfortunately been admitted into a mental hospital, where most of the patients' complaints are invariably put down to imagination and persecution mania. No doubt they would have died of their organic disease, but not before developing mental symptoms which would of course have justified the original false diagnosis of anxiety neurosis—I am, etc.,

London N W 11

A LIONEL ROWSON

Primary Agranulocytic Angina

SIR—Thank you for your kindness in publishing my paper on agranulocytic angina in your issue of Dec 14, 1946 (p 897), as well as for your courteous and interesting annotation (p 905). I have since ascertained through the kindness of Dr S B Benton, the deputy medical superintendent of the Nottingham City Hospital whom I must thank for allowing me access to the follow-up records, that the patient in question turned up unexpectedly after a year's absence. His condition remains satisfactory. There are no signs or symptoms, while his total white cell count is 8 000 per cmm—the differential count being polymorphs 76%, lymphocytes 24%—thus adding weight to our suggestion of spontaneous recovery.

I feel, however, that the pentnucleotide did help not a little in tiding him over the acute stage and that it should not be absolutely withheld, especially in these cases where septic complications, which of course demand penicillin and perhaps pyridoxine, are not a major factor. I agree that in cases where the causal factor is a chemical poison such as thiouracil or sulphonamides the immediate cessation of administration of the poison will do more perhaps than anything else to get the marrow going again, for obvious reasons—I am, etc.,

Nottingham

I M LIBRACH

Haematological Heresy

SIR—I was greatly interested in the article by Dr R R Bomford (Dec 28 1946 p 996) under the above title. It stimulated thought on a problem which most of us have regarded as settled beyond reasonable doubt, and it is right that all hypotheses should be subjected to such attacks, whether or not they emerge triumphant or are superseded by newer theories more consistent with the known facts. In the case of the maturation theory of the causation of pernicious anaemia the evidence in its favour is so strong as to make it well nigh incontrovertible. However, like Dr Bomford I have often been at a loss to explain the high level of blood destruction which is apparent from the evidence of increased phagocytosis of red-cell elements, the haemosiderosis of liver, spleen and other organs, bilirubinaemia and methaemalbuminaemia (Fairley 1941) and from the increased excretion of urobilinogen. Nevertheless it hardly seems necessary to abandon a well-founded theory on this account if, as I believe it can be modified in such a way as to explain fully these findings without delving into the limbo of hypothetical toxins, as suggested by Dr Bomford.

It has often been shown that the fragility of the red cells in pernicious anaemia is not increased, but there is no evidence that the late precursors of the red cells, the haemoglobinized megaloblasts, are not more fragile than normal, or at any rate more liable to phagocytosis in the reticulo-endothelial system. If this is in fact the case it may well be that lack of the haematinic principle disturbs erythropoiesis in such a way as not only to produce premature haemoglobinization but also to render the cells more liable to destruction—probably at the stage that extrusion or disruption of the nucleus takes place. If I may adopt Dr Bomford's simile of the motor-car factory, it is not the lack of an essential part which is the trouble but the provision of a faulty part rendering the car liable to explode when the starter button is pressed. We then have the position where there is an increase in the rate of production to compensate for the shortage of cars or red cells, in circulation and an increase in "scrap," as evidenced in the body by haemosiderosis, bilirubinaemia, etc. This theory also has the advantage that it

readily explains the lack of reticulocytes in the circulating blood of an untreated case and the dramatic reticulocyte response to liver therapy, even accompanied as it sometimes is by a shower of nucleated cells, since, when the cells are no longer destroyed at the stage when the nucleus is lost, there is bound to be a rapid increase of very young cells in the blood stream.

I am aware that this theory has no experimental backing, but at least it involves less alteration in an otherwise adequate theory than the alternatives suggested by Dr Bomford. Perhaps in these days of tracer elements it may be possible to settle this question once and for all, but in the meantime we must be grateful to Dr Bomford for renewing interest in this subject—I am, etc.,

Fairley N H (1941) *Quart J Med* 10 95

SIR—During the war I found myself transformed from a clinical biochemist into a haematologist responsible for teaching up to 120 students a year. Being initially profoundly ignorant of the subject, and my haematological colleagues being inaccessible I was forced to study the literature and to supplement this wherever possible by my own observations. The maturation arrest theory of pernicious anaemia as Dr R R Bomford (Dec 28 1946 p 996) shows, unable to co-ordinate many of the facts already known. The Ehrlich Ferrata (1914) hypothesis of erythrooiesis (that is, that in pernicious anaemia an abnormal series of red cell precursors—megaloblasts—appears) explains the morphological facts and La Cour (1944) showed that in the marrow of untreated pernicious anaemia mitotic figures were increased and that 70–80% of these were abnormal, treatment with liver extract returns the marrow to normal.

These observations suggest that the liver principle does in fact act on the marrow and that its function is to permit normal mitosis, in its absence abnormal mitosis occurs and produces abnormal cells probably at a faster rate than in the normal. The high urobilin excretion in pernicious anaemia demonstrates that a haemolytic process of considerable intensity is occurring simultaneously. Erythropoiesis can proceed at rates six times greater than normal as is shown by the response to splenectomy for acholuric jaundice during or just after a crisis (e.g. Roth, 1927) and the hypothesis that urobilin is derived from haemoglobin precursors is unsupported by evidence and is chemically most improbable. This means that the theory of abnormal erythropoiesis proceeding at an increased rate and the theory of increased haemolysis are both true and must be reconciled. The hypothesis of selective lysis of abnormal reticulocytes is most attractive. On my reading of the original theory abnormal cells are formed and destroyed by the normal processes of the body more rapidly than are normal cells, and the anaemic state which develops is the resultant of these two processes. To invoke haemolytic toxins may be necessary for the explanation of dibothriocephalus anaemia and for that associated with stagnant loops of bowel, but is surely unnecessary in true pernicious anaemia.

Many haematologists fail to distinguish between normoblastic and megaloblastic erythropoiesis. This fundamental error arises from Doan Cunningham and Sabin (1925) who misused the term megaloblast in that, ignoring the rules of scientific nomenclature, the 30 odd years priority of Ehrlich who applied it to a rather mature cell found in pernicious anaemia and the 12 years priority of Ferrata and Negreiros Rinaldi who extended it to the whole series of abnormal red cell precursors found in pernicious anaemia, they redefined it as the most primitive erythropoietic cell of foetal and adult haemopoiesis. Sabin soon identified her 'megaloblasts' with those of Ferrata and the theory of maturation arrest is a logical necessity of this erroneous identification. It was naturally soon "confirmed" by studies on material from which true megaloblasts (Ehrlich Ferrata) are known to be absent. Not until 1938 did Sabin admit that cells morphologically identical with the megaloblasts of pernicious anaemia are not present in normal rabbit marrow (see Jones, 1943).

It is surely true that the sections on erythropoiesis found in the textbooks should be remodelled to agree with the facts. The maturation arrest theory appears in all the textbooks of

physiology with which I am acquainted, and it does not agree with the observed facts. A lead has been given by Wintrobe and by Whitby and Britton. Let us now persuade the physiologists to describe theories which agree with observation, in this way they would ease the task of their students and of their colleagues in the field of clinical haematology—I am, etc.,

Diet and Canine Hysteria

SIR—The preliminary report (Dec 14, 1946 p 885) of Sir Edward Mellanby on the experimental production of the hysteria syndrome in dogs by feeding agenzized flour is of very considerable interest to the veterinary profession. Although experience had forced the majority of practitioners to consider the causative factor to be located in wheaten products, yet few appeared to have any idea what that factor was or how it worked. Sir Edward's findings will also prove to be of the greatest assistance to those who are studying canine encephalomyelitis and distemper virus encephalitis, since in both these diseases the hysteria syndrome frequently complicates or rather is superimposed on, the other symptoms in such a way as to puzzle the keenest observer.

The purpose of this note is to suggest the precaution that before any feeding experiments on human volunteers are conducted a thorough study should be carried out of the histology of the central nervous system of (1) heavily agenzized dogs and (2) agenzized dogs infected by distemper virus, for the following reason. During the course of a study of the pathology of disseminated encephalomyelitis of the dog in 1927-9 it was demonstrated by J R Perdrau and L P Pugh (*J Path Bact* 1930, 33, 79) that four out of the fourteen cases investigated showed demyelination of the type commonly found in subacute disseminated sclerosis, and, just as in the case of its human counterpart, the hypothetical demyelinating toxin could not be discovered. In these circumstances it does not seem beyond the realms of possibility that Mellanby's toxin may well open up a still wider field of greater importance than would it first appear—I am, etc.

Sulphadiazine in Infantile Gastro-enteritis

SIR—With reference to Dr C J Penny's letter (Dec 28 1946 p 1006) regarding the efficacy of sulphadiazine in infantile gastro-enteritis, my experience with sulphaguanidine in the treatment of acute bacillary dysentery may perhaps be of interest. While acting as medical officer in charge of the dysentery wing at Changi prisoner-of-war hospital, Singapore from June, 1944, to September, 1945, I carried out a controlled experiment to test the relative efficacy of sulphapyridine and sulphaguanidine in acute bacillary dysentery. Sulphapyridine was extremely effective in practically all cases in doses of 3 g daily for two days. Sulphaguanidine in doses up to 15 g daily (the most we could afford from our small stock) was ineffective in severe bacillary dysentery and was far slower in controlling the symptoms in moderate cases. From these results we concluded that the action of sulphaguanidine was not local but depended upon the amount absorbed into the blood stream. I may add that over four thousand cases of dysentery were dealt with during this period and we had ample clinical material on which to prove the result of the experiment—I am, etc.

Tuberculosis in Industry

SIR—In his paper on "Tuberculosis in Industry" (Dec 28 1946 p 975) Dr Frederick Heaf refers to the detection by mass radiography of symptomless cases where laryngeal swabs or gastric lavage show tubercle bacilli in conjunction with minimal radiographic lesions. Dr Heaf asks: "Are we to regard them as active infectious cases with respect to their employment and need for treatment?" He answers his own question: "Personally, I think we should take every precaution

to prevent the spread of infection and to arrest the disease, for we have a good chance of curing these cases, and that a compromise between employment and treatment while activity exists should be avoided. [The italics are mine.] In the past too much time and skill have been wasted on the impossible task of restoring the advanced case to health when consideration of the morbid anatomy would have caused us to direct our energies to efficient treatment of early cases."

With that last sentence I agree, but I dissent from the implied suggestion that the former group of cases should occupy sanatorium beds 'while activity exists'. Wherein lies the activity? Not in symptoms since none are present, but in minimal radiographic signs and a few tubercle bacilli detected with difficulty. At this stage there is little risk of the spread of infection. At this stage we have a good chance of curing these cases. We certainly have. In many of them the disease becomes arrested—a word preferable to cured—without any treatment in the ordinary therapeutic sense. So in the first instance these are cases for observation until the need for treatment is shown to be necessary.

Mass radiography has confirmed the dictum of Sir Clifford Allbut at the beginning of the century—that many patients recover from pulmonary tuberculosis unbeknown to themselves or to their doctor who was treating them for something else. Moreover mass radiography reveals gross calcified lesions in persons who so far as they knew never had a day's illness or lost a day's work. The findings of mass radiography are certainly causing some apprehension because they have shown that the essential problem of tuberculosis is as yet unsolved—I am, etc.

HALLIDAY SUTHERLAND

Infertility: Cervical Impenetrability

SIR—A review of the present state of investigation and treatment of human infertility, a problem of national and human importance, was presented in the *Journal* of Oct 26 1946 (p 618). The conclusion reached was that although more accurate diagnosis has been achieved the result of treatment on the whole is unsatisfactory.

I wish to limit the following remarks to those cases of infertility (a not inconsiderable number) in which the only discoverable fault is the failure of viable spermatozoa to penetrate and survive in 'ovulatory' cervical mucus. It is suggested that either the interface (the point of contact of the two immiscible colloids semen and cervical mucus) or unknown physico-chemical factors within the mucus devitalize the spermatozoa and they die. These physico-chemical factors of mucus have up to the present time been comparatively neglected. The solitary published work bearing on this aspect of the subject appears to be *Observations on Certain Rheological Properties of Human Cervical Secretion* (Clift A F, *Proc roy Soc Med* 1946, 39 1)—an investigation carried out in the Nuffield Department of Obstetrics and Gynaecology, Oxford. Cervical mucus is secreted continuously throughout the menstrual cycle, and its quality or consistency undergoes cyclical changes due to the influence of hormones. It is known that this secretion is influenced both in quantity and quality by the administration of oestrone.

When considering a body secretion such as cervical mucus we must remind ourselves that secretions are not true fluids; they are complex rheological systems and as such they are characterized by rheological properties—e.g. anomalous viscosity, elasticity, flow elasticity, *Spinnbarkeit* (fibrosity), tack, stickiness, adhesiveness, plasticity, work-hardening and possibly rheopexy, thixotropy, birefringence, etc. Such is the complexity of the cervical mucus. To quote from D Arcy W Thompson's *Growth and Form* (London 1942) under the heading of Rheology and Colloids:

'Where the bacillus lives' [and here we may substitute the word spermatozoa] gravitation is forgotten, and the viscosity of the liquid, the resistance defined by Stokes's law, the molecular shocks of the Brownian movement, doubtless also the electric changes of the ionized medium, make up the physical environment. The predominant factors are no longer of our scale; we have come to the edge of a world of which we have no experience and where all our preconceptions must be recast.'

A more analytical study of the rheological properties of cervical mucus is essential to a clearer understanding of the

relation of variations in consistency of cervical mucus to penetrability by spermatozoa. Rheology—i.e., the science of the deformation and flow of matter ($\rho\epsilon\iota\sigma\tau\epsilon\lambda\omicron\gamma\iota\alpha$)—offers conceptions based on special properties of molecules, such as polarity and length, as theoretical aids to assist in understanding these properties. Efforts are being made to replace rough subjective tests for these rheological properties by more accurate objective measurements—e.g., the Scott Blair meniscope, designed for the measurement of the flow-elasticity of human cervical mucus.

Prof G R Cameron, in his address on cellular pathology given at the Centenary Celebrations of the Pathological Society of London (*Proc Roy Soc Med*, 1946, 39, 827), said: "We are passing from a period of physico-chemical investigation into the submicroscopic period, we are coming to think of protoplasm in terms of giant molecules and mono-molecular surface films and their physico-chemical properties governed by molecular arrangements. This stage is progressing from a relatively simple colloid chemistry to the involved considerations of high polymer chemistry. The methods of such special fields as polarization optics, x-ray crystallography, and electron microscopy would seem to be essential for the investigation into protoplasmic reactions." What Prof Cameron says of the approach to the investigations of protoplasmic reactions can equally be applied to the study of cervical mucus. The biochemistry of bovine cervical secretion is proceeding apace but no similar chemical investigations have been undertaken with human cervical mucus.

The study of this aspect of infertility is therefore a very comprehensive one. No isolated gynaecologist or biologist working individually can hope to approach the subject from all points of view. Access to the appropriate expert opinion should be made available through a team of workers comprising rheologist, biologist, chemical pathologist, endocrinologist, together with a gynaecologist. Medical personnel interested in the study of infertility will appreciate the important observations and "invasion tests" contributed by Mary Barton and B P Wiesner in their article *The Receptivity of Cervical Mucus to Spermatozoa* in the *Journal* of Oct 26, 1946 (p 606).

Discoveries in research and therapeutics go hand in hand (Samuel Wilkes). The solution of the problem of infertility would relieve the 'anxiety, unhappiness, and bitterness that childlessness can cause'—I am, etc.,

A F CLIFT

Oedema of Vulva due to Toxaemia of Pregnancy

SIR—The interesting account (Dec 28, 1946, p 988) by Dr J P Bush of a case of oedema of the vulva recalled to my mind a similar case, with a less fortunate ending, which was forced on me at an early stage in my career. In 1934 I was doing my first assistantship in general practice in an isolated and wild country district of north-east England. The country side was delightful, the practice widespread, but the nearest hospital of any sort 28 miles distant.

One spring morning one of the other doctors in the area notified me that he was to be away for the day and asked me to do any urgent work for him that might materialize. He told me that there was a primigravida, not due for several weeks, about whom he was rather worried, as she had considerable oedema and very heavy albuminuria, whom he would see before he left, but said it was very improbable I would have to call inevitably of course a call came to that case in the late afternoon, and I got there to find the girl was having vague pains which her mother thought might be the onset of labour.

I had never seen the patient before and my dismay can hardly be imagined when I discovered that there was such gross oedema of the vulva (as well as of legs, thighs, and abdomen) as to make vaginal examination completely impossible. In a cottage deep in the country and far distant from hospital, methods very different from those possible at St Thomas's were necessary, and under local ethyl chloride anaesthesia I incised both labia, releasing a large jet of pale yellow fluid under pressure from each side. After 15–20 minutes the ballooned vulva had subsided enough to allow of vaginal examination, which confirmed that the first stage of labour was well advanced, and an exceedingly anxious assistant discussed with the patient's mother the choice

between the chances of the patient arriving safely at hospital for Caesarean section or of keeping her at home with safety.

With time obviously short it was decided to carry on at home, and within an hour and a half a live child was born only to reveal—what had been hidden by the gross oedema of the abdominal wall (and 'ascites')—that another was to follow. The second child, a breech, followed safely within the next 15 minutes, and all so far had gone well. But an hour later the patient went into her first eclamptic fit and from then on till her death 36 hours later fits followed at pretty regular hourly intervals despite all the usual treatment.

This, Sir, is a sad story and should never have happened. I tell it so that others who read Dr Bush's case report may not be deceived into taking the slightest and very unwarrantable risk of temporizing or delay. That way lies disaster—inevitably—I am, etc.,

W H G

Prevention of Infant Deaths

SIR—Dr J Tudor Lewis (Dec 14, p 893) discussing a scheme to attain improved liaison between hospital and home maternity services in order to salvage a certain number of infant deaths, quotes from seven case histories to illustrate his view point, under the heading 'The Need for Liaison'. The illustrative cases cited, however, predominantly indicate that the main onus for the infant deaths in at least five of the cases must be related back to their too early discharge from hospital. It is hard to conceive how the premature infants mentioned could have become established during their short hospital stay, and irrespective of the home conditions they had to contend with afterwards their chances of survival were unnecessarily gravely prejudiced by their early discharge. Despite the all too common excuse of shortage of beds in obstetric units, surely it is a false economy to prejudice these premature infants' chances of survival at the expense of a further week's or ten days' stay in hospital. Another disturbing feature was the frequent incidence of anaemia of the mothers in the quoted cases. Dr Lewis does not state whether the blood counts were taken ante or post partum, but from the histories they would appear to have been estimated prior to delivery. There is no indication given whether any measures were instituted to correct these anaemias, although the comments he made tend to suggest that they were not.

In our experience quite the commonest maternal cause of the failure of a mother to make a success of rearing her child is post partum anaemia and debility. It would appear, therefore, that the additional burden of a premature infant not yet fully adapted to its extrauterine environment, was being placed on an already debilitated mother, who, no matter how willing she may have been in spirit, was physically unable to cope with her task. Case 6 illustrates how immense such an unfortunate parturient woman's task can be. She poor soul, had an unpleasant antenatal period from hyperemesis, and in addition to being of a naturally apprehensive, nervous disposition was also suffering from some degree of general debility. She could not reasonably be expected, therefore, to be in any better health after her delivery than before it, but in addition to being sent home on her ninth post partum day, with a small premature infant, she was expected to feed it every two hours. It is difficult, thus, to concur with Dr Lewis when he states that 'clearly the death of each one of these infants was caused directly or indirectly by the poor 'mothering' and care it received after (italics ours) leaving the hospital or maternity unit.

Could it not be more justifiably said that the death in the case of each premature infant be related primarily back to the too short period of institutional care?

The provision of a hostel for the transitional stage between hospital and home periods, to enable the difficult and premature infants to be 'hardened off,' has the definite advantages claimed for it and these advantages, we think, are not outweighed by such disadvantages as cross-infection and epidemic types of illness provided reasonable care is taken by the charging maternity unit that these infants are themselves

and have not been in contact with any such types of infection. Much, however, can be done during the antenatal period to stimulate parental interest and foster both 'mother and faith

craft by the institution of simple lecture demonstrations for both parents these being developed as a part of the antenatal service. This interest can be further developed in hospital in the case of a mother with a difficult or premature infant by making her responsible under supervision for the entire care of her baby during the additional period of hospital stay allowed for the infant to become established. The hospital almoner also is of great assistance in the welfare of both mother and infant. It is our practice to have the home circumstances of each case investigated by the almoner during the lying-in period, and to be satisfied that sufficient home help and reasonable home conditions exist before discharging the mother and infant from hospital. Although Dr Lewis states that the liaison obtained by notifying the Health Department of such an infant's discharge and requesting an early visit from the health visitor is ineffective we have found that in practice by ensuring a home visit on the day following discharge, the continuity of supervision of the mother as to the care of her infant is preserved with reassuring results.

We feel therefore that the major responsibility in the establishment of small difficult or premature babies after birth lies primarily with the maternity unit and that such a unit must be fully satisfied when such infants are discharged home that they are fit to withstand the less suitable conditions in the average household, and that in addition their mothers must be fit at least physically, to look after them.—We are, etc.,

I M HARKNESS
J B COCHRANE

"Anaesthesia" or "Analgesia"?

SIR—Dr F W Roberts in his letter (Dec 28 1946 p 1007) raises two points to which I feel I must reply in self-defence. First he states that 'novocain' and other local anaesthetic agents do not abolish touch deep pressure and thermal sensitivity and are therefore true analgesics. I believe that they abolish all these and are therefore true anaesthetics which is the base of the reasoning that appears faulty. Authority for this may be found in any textbook and I would quote Langton Hewer's *Recent Advances in Anaesthesia and Analgesia* fifth edition p 143 where reference to the literature is given. Secondly if I had meant intravenous anaesthesia I would have said so. Reference to the slow drip infusion of dilute procaine in glucose saline is given on p 139 of the same work.

Whether analgesia is an ugly word is of course purely a matter of opinion. It is much more frequently written than spoken which suggests that others besides myself find it so and I have not yet heard of its being used as a girl's name which is a touching tribute to the beauty of the word anaesthesia. As a matter of fact I find from Liddell and Scott that there is no distinction between the words in Greek although the adjective derived from analgesia was used to mean 'very painful'. This might be held by some to justify the use of the word to describe the occasional nerve block which does not come off.—I am etc.

Colchester

J N FELL

Abacterial Pyuria

SIR—Dr D P Wheatle, (Nov 30 1946 p 837) brought attention to the fact that no mention had been made of penicillin in the treatment of abacterial pyuria. I have treated several of these cases with large doses of penicillin (over a million units) and can record only a temporary slight improvement followed immediately by relapse on cessation of penicillin administration. In contradistinction to Capt Meldsend R A M C I have always found evidence of prostatic infection with the presence of pus cells and a lessened epithelial content in prostatic beads.

Search for the *Trichomonas vaginalis* has been negative on each occasion despite repeated examination for the same. I have always regarded these cases as infection of the bladder gone by simple extension from a posterior urethritis and prostatitis. Two cases gave a history of non-specific urethritis in which high urethral lavage had been administered. I have treated several of these patients with intravenous oarsphenamine and while recording an improvement and clearing up in the majority must submit that some

responded only to long-term hospitalization and rest. I should like to add that all were subjected to complete pathological and physical investigation to exclude other causes, and only in the end labelled abacterial pyuria.—I am etc.

Pre-operative Blood Transfusion

SIR—Many surgeons have wisely adopted the pre-operative blood transfusion to hasten recovery and to minimize the risks attendant upon operation in the anaemic subject. It would seem however that some of these surgeons or their house-surgeons are unnecessarily delaying the giving of these transfusions until almost the immediate pre-operative period. I would suggest that such a delay except in a case of active haemorrhage is not in the best interests of patient or surgeon.

My reasons for making this suggestion will be obvious to all surgeons but for those who would appear to have overlooked them I append the following: (a) Even under the best conditions a transfusion may be followed by a reaction. This complication is always undesirable but especially so just before an operation. Even in the absence of reaction a transfusion places a considerable physical and mental strain upon the patient. (b) Attention has recently been drawn in your columns to the value of adequate nutrition during the week or two preceding operation. Anorexia a frequent accompaniment of chronic anaemia is often not overcome until the anaemia has been satisfactorily treated. Moreover it is surely desirable that the patient should be given the advantages ensuing from improved oxygenation of vital organs for a greater period than the 24 hours or less before a major surgical ordeal.

For these reasons I would plead that the transfusion of surgical cases complicated by anaemia should be undertaken at least one week prior to operation. It may be objected that the adoption of such a measure is quite impracticable because of the shortage of hospital beds. It would seem probable however that the increased time spent in hospital during this preparatory period would be counterbalanced by the hastening of recovery following the operation. In some instances it may be of value to admit the patient for two or three days only for the transfusion and then to re-admit for the actual operation.—I am etc.,

Bristol

GEOFFREY H TOVEY

Conservative Treatment of Perforated Ulcer

SIR—I was interested in the summation and verdict on the above given in the annotation in the *Journal* of Dec 21, 1946 (p 950). During the past three years I have been investigating these cases from the radiological and clinical aspect and in a paper to the Faculty of Radiologists in June, 1945 I suggested in view of the observations to date that the conservative line of treatment should be given a fair trial. The idea was ridiculed at the time and it was with considerable difficulty that some of my surgical colleagues were persuaded to try the method. The investigations were on the acute abdomen with particular reference to the presence of free gas in the peritoneal cavity.

The radiological detection of free gas in the uppermost dependent portion spells only one thing—a perforation somewhere in the gastrointestinal tract. The subdiaphragmatic gas gives us a fairly accurate estimate of the degree of gas-leak and consequently an idea of the size of the perforation. I would be interested to know the views of surgeons as to the value attached to the presence of free gas in the diagnosis of perforation and if they have utilized the volume of gas present as an index of the degree of leak and size of perforation. Assuming there is a gas-leak in the majority of perforations it would appear to me that the estimation of volume would be of assistance in determining the suitability of the case for conservative treatment or otherwise. The gas may vary from a millimetre to a couple of inches (5 cm) and a check can be made during the first few hours as to increase or otherwise. Unfortunately there is at present no method of indicating the stoppage of leak but we can at least indicate any increase. The gas is absorbed slowly and may take according to the volume anything from five to fourteen days. The direct or scout r-ray examination should be helpful not only in assessing the degree of leak but also in the differentiation between intra- and ref-

peritoneal perforation—the latter, unfortunately, a more serious drama and with a very high mortality rate

Two aspects of the radiological investigations impressed me: the number of cases of spontaneous recovery with conservative treatment, and the frequency of perforation in peptic ulcer, without the knowledge of the patient, his medical attendant, or surgeon. Perforation is not always the dramatic picture it is painted and may manifest itself as an acute and transient exacerbation of the ulcer symptoms, when the patient seeks the attention of his relatives, the usual alkaline mixture and rest in bed before calling his medical attendant. An examination of these cases will reveal minimal free gas—a perforation with rapid sealing. The following morning he is having his breakfast in bed.

I feel confident that peptic ulcers perforate more frequently than we imagine with quick and transient symptoms and if a check up is made in all cases of acute exacerbation of ulcer symptoms free gas will frequently be found. The frequency of the perforating type of ulcer found in routine barium meal examinations would tend to confirm this, and a careful check up on the past history may reveal a short period of acute exacerbation of symptoms. The patient may state he remembers a period when he was doubled up with pain, lasting perhaps for two hours. There is little doubt that he has perforated. Every acute or subacute abdomen should, on admission to hospital, have a scout film of the abdomen which must be taken in the upright, semi upright or lateral decubitus, in order to show free gas or indicate the presence of bowel obstruction. The absence of free gas strongly contraindicates perforation.

My admiration goes to those surgeons who have at least the courage to investigate the field of conservative treatment. Please do not let us precipitously condemn the method, rather let us proceed cautiously with an open and balanced mind, for the treatment is still young, and half a century of surgical tradition is difficult to change. As you state, a perforation is the surgeon's apotheosis, dramatic in the extreme, with the patient gravely ill and shocked. The addition of laparotomy is only too often the last act of the drama: the dropping of the curtain—I am, etc.,

Hill

J E BANNEN

SIR,—As you point out in the annotation (Dec 21, 1946 p 950) on the conservative treatment of perforated peptic ulcer, the mortality rates disclosed do not compare with those obtainable by surgical closure. There is other evidence against the adoption of this method as a routine procedure. It is not a recent innovation everywhere and has been practised on selected cases in at least two surgical units to my knowledge in Glasgow for over fifteen years.

The treatment is reserved—as Hedley Visick suggests—as reasonable—for patients in whom the initial spill is small and the signs suggest that the effusion is not increasing in size. Cases of this type amount to less than 5% of all ruptured ulcers. They are nursed on an inclined plane or in Fowler's position adequately morphinized, and nourished only through the rectum for forty-eight hours thereafter a conservative oral regime is started. This method has not had an extended application for the following reasons.

A study of the clinical pathology at operation shows that when a ruptured ulcer seals itself before laparotomy the seal is formed by adhesions to some structure of the biliary tract, commonly either liver or gall-bladder. For obvious reasons these are unsuitable structures to form the floor of a chronic ulcer. Infrequently the lesser omentum, mesocolon, or colon, and only rarely the omentum fills the gap. The last step in operative closure of a ruptured ulcer is or should be the completion of the repair by the interposition and fixation of a tag or tags of the lesser omentum between the sutured ulcer and neighbouring viscera. This has the double purpose of preventing less desirable adhesions and providing a possible source of enrichment to the blood supply of the ulcer-bearing area.

There is a further consideration in favour of operative closure. The removal by suction of effusion and particulate matter may not be necessary, but if Rutherford Morrison's pouch is sucked dry and the suprahepatic spaces similarly evacuated the convalescence is eased by the withdrawal of the highly irritant chyme from the peritoneum and the incidence

of subphrenic abscess lowered well below that published by Visick for conservative treatment.

In conclusion it is regrettable that Murphy's route for fluid replenishment is *demiode* among surgeons. When complete gastric rest is required absolute starvation combined with a constant-drip rectal saline will maintain the fluid balance more readily, more equably, and with greater safety to the patient than the alternative method. Hypoproteinaemia can if necessary be dealt with by intravenous plasma or reconstituted serum. Suction drainage through an indwelling nasal tube is uncomfortable while saline administered intravenously serves principally to stimulate renal function and always carries the danger of pulmonary oedema—I am, etc.,

Glasgow

A IAN L. MAITLAND

SIR—Courage is needed to sit on a perforated gastric ulcer, for most of us have been taught that a perforated peptic ulcer is a paramount emergency which needs surgical treatment at once, and any failure to effect this represents the dropping of a major brick, but to some Mr A Hedley Visick's most interesting article (Dec 21, p 941) on its conservative treatment will be hailed with much approval—though this does not apply to his remarks on bigger and better gastrectomies. It is a hard job sometimes to practise masterly inactivity, and some of his observations will act as a powerful encouragement. Sometimes activity seems to run in inverse proportion to experience. One of my duties is to attend a large body of men for whom a considerable first-aid department exists. With one exception the first aiders know little of medicine and recently they have been given a preparation of gentian violet—I imagine as an antiseptic. It produces a striking appearance and every kind of disability is treated with it. So far as I know it does no harm. Patient and attendant are well satisfied at the dramatic evidence of therapy and so it may well do good. It is a hard and thankless task to do nothing.

The use of morphine for the pain of a perforation seems sensible enough, though I have the feeling that the stomach lavage, the Ryle tube, and the sulphonamides might well be omitted. But there is the danger that it will be considered by friends of patients and attendants that not enough is being done. Mr Visick's article will sustain them in their conservatism to leave Nature to repair its transgressions. It is a relief to know that the peritoneum can deal with many strange and unexpected foreign bodies. Although I have seen my fair share of the catastrophes to which the human frame may be heir, withal I cannot resist a sneaking attraction for Wordsworth's simple faith 'that Nature never did betray the heart that loved her'—I am, etc.

E GALLOP

Wholesome Bread

SIR,—It is gratifying to find no less an authority than Sir Edward Mellanby drawing attention (Dec 14 1946 p 88) to the harm that is done to our food by certain organizations who put profits before public health.

For their own convenience the millers of this country by means of subtle propaganda have succeeded in building up a demand for wheat flour that has had the germ and pericarp removed and is in consequence considerably inferior as an article of diet to the wheat flour eaten by our grandparents. We are then faced with the absurd situation of the public spending enormous sums of money on vitamin B products many of which are prepared from the very substances the millers have removed while the widespread constipating effect of white denatured flour is relieved by paying certain firms to replace in our diet the selfsame bran that was removed in order to give wheat flour an unnaturally white colour.

But this is not the whole story. Having created an artificial standard of whiteness as a sign of good quality (by which standard strychnine would be regarded as a much more wholesome substance than cocoa) the millers were forced to put this fallacious teaching to its logical conclusion by saying that the whiter the flour the greater its food value. Unfortunately wheat flour is not pure white even after extracting important food elements which give wholemeal flour its brown colour and so a further artificial process of bleaching is introduced in order to render flour dead white in colour.

Controlling the asthmatic spasm

In asthma and other allergic disorders no treatment for the attack has yet disturbed the pre-eminence of adrenaline, the physiologically specific, natural inhibitor of those disorders, but, when the attacks are frequent and of considerable duration, the use of the hydrochloride has the disadvantage of making frequent injections necessary, owing to its relatively transient effect.

With the introduction of **Hyperduric** ADRENALINE this troublesome frequency of injection has been overcome by the combination of the active base with mucic acid (the distinctive feature of the Hyperduric series) and the action of the resulting adrenaline mucate is observable for 8 to 10 hours.

The complementary treatments for colds

THE therapeutic properties of both Silver Vitellin and natural levorotatory Ephedrine are well known. In Argotone they have been successfully combined into a stable solution in normal saline providing disinfection and decongestion in the treatment of nasal affections.

In the common cold there are other distressing features—headaches stiffness and fever. To relieve these symptoms the oral administration of Deltamin tablets is recommended.

Together, Argotone and Deltamin offer a complementary treatment for the common cold.

(Calciferol B D H)

It is of the utmost importance to prescribe highly-purified calciferol when this substance is required for administration in large doses. Radiostol is calciferol in its purest form and it is suitable, therefore, for administration in the large doses necessary in the treatment of lupus vulgaris and arthritis. Radiostol is issued in capsules each containing 50,000 i.u. (for use in the treatment of lupus vulgaris) and in solutions containing 100,000 and 200,000 i.u. per gram respectively (for use in the treatment of arthritis). Radiostol is available also in solution (Liq. Calciferolis B.P.) and in pellets each containing 3000 i.u. for the prevention and treatment of rickets. Further information is available on request.

ARRESTING

The Male Climacteric BY PERORAL HORMONE THERAPY

The mental fatigue and diminished bodily energy which characterise the male climacteric respond readily to male hormone therapy in the form of ORAVIRON (British Schering brand of methyl testosterone in tablet form). Depression and nervous instability are eliminated, and the general condition, both mental and physical, shows a steady improvement.

ORAVIRON is presented in tablet form in the following sizes:
TUBES of 20 x 5 mg tablets
TUBES of 20 x 10 mg tablets
BOTTLES of 100 x 5 mg tablets
BOTTLES of 100 x 10 mg tablets

*For Inflammatory Conditions
of the Nose and Throat*

Glucio-Fedrin

The development of vehicles suitable for medicaments employed in the treatment of inflammation of the nasal mucosa has been the subject of special investigation in the P. D. & Co Laboratories. An isotonic dextrose solution containing menthol, Chlorotone and ephedrine was found to be superior to other preparations tested.

Such a combination, together with 'Phemeride' (an antiseptic which exhibits high germicidal activity against pathogenic bacteria commonly found on the nasal mucous membrane), is available under the name 'Glucio-Fedrin'. This is suggested for use as a vaso-constrictor in diagnostic investigations of the nose and accessory sinuses as well as for the treatment of the common cold, hayfever and other forms of rhinitis.

SAVE PRECIOUS TIME AND REDUCE ROUTINE WORK...

Few professional men find time as precious as the doctor.

One of his greatest problems is to apportion his day so as to cope with the many and pressing demands upon his professional life.

Yet even the medical man has some essential clerical work. Case histories, clinical records, accounts and the like have to be maintained.

Medical men, being so pressed for time, will welcome the news of specially designed visible records—especially since they cut down clerical work by half and reveal instantly those salient facts the doctor needs to know.

There are two main records: the Case History Card and the Accounts Card. Each patient's record is individually suspended on steel hangers in cabinets or books. Thus, while the patient actually sits before you, you have his history—name, address,

occupation, past medical history, family background, etc. And there is ample provision for entering clinical notes, diagnoses, prescriptions and the like. The Accounts Card details all consultations, medicines, dressings, visits, special items (such as confinements) and similar matters. These records can either hang together in pairs or be kept separately.

In addition, the visible part of the records can be utilized to carry warning signals of impending visits of cases that need close watching, overdue accounts, etc., as well as any other special facts which you may want to keep before you.

Yet the all-in cost is only a matter of pence per record, including the cabinets and books to house any number—from forty to a thousand or so. (There is a specially handy size for use when visiting patients.)

Don't waste time writing a letter—simply write on your card or letter-heading the words "Records please" drop into an envelope and address it to

CONTROLLED Fever Therapy...

BY the Marconi Theratherm, artificial fever is induced electrically in the shortest time consistent with safety. A powerful ultra short-wave generator of advanced design, the Theratherm is easily operated to apply maximum controlled energy to the patient.

Features include —

- Simple yet flexible control
- Output ample for all requirements
- Ultra-short wavelength
- Operated with either condenser plate electrodes or treatment cable
- Neon indicator ensuring precise "tuning" of patient's circuit
- All electrodes enclosed in unique plastic having negligible loss at working frequency

be it noted, not for food or health purposes but for commercial money-making only. Still pursuing this self-interested propaganda the great commercial interests concerned described this process as an "improvement" and the chemicals used as "improvers," and it is here that I would like to enter a plea for the abolition of this unnecessary interference with our food and for the accurate use of English words, especially in scientific journals.

Hitler gave us many examples of how to disguise unpleasant truths by substituting mild-sounding words, as when he described his cold-blooded murders as "liquidation", and when commercial firms adulterate our food with poisons which have caused madness and death in numerous dogs let us call it quite plainly "adulteration" and not "improvement"—I am, etc.,

H TUDOR EDMUNDS

Sterilization of Syringes

SIR—The evidence in favour of boiling as opposed to fluid antiseptics for the sterilization of syringes is overwhelming and is quite untouched by the anonymous impressions described by "EX-RAMC" (Dec 14, 1946, p 920). Rather in the spirit of offering testimony against a method that has already been found guilty but not yet condemned to die, the salient points may be stated as follows.

For many years past in venereal disease clinics there has been a small but definite incidence of jaundice, but this condition became more and more common in the Services after 1941, reaching a very high rate in the years immediately following.¹ Its nature and mode of infection were at that time unknown, but it was in many quarters considered as primarily due to arsenic. In 1943 Bigger showed that the existing methods of syringe sterilization by means of spirit were in fact far from effective, and he and MacCallum² independently suggested that this faulty sterilization might be in part responsible for the jaundice. The following year, Salaman *et al.*³ showed that if the syringes were autoclaved and strict antiseptic precautions adopted then this disease could be practically eliminated from a clinic. (This was later amply confirmed by Laird,⁴ who employed boiling.) Boiling of syringes became compulsory for intravenous work, and the subsequent drop in the incidence of jaundice in a department where previously the rate had been high has been described.⁵ While the policy was approved it was not as vigorously pursued in respect of intramuscular injections not only on account of a relative shortage of syringes but also as it was considered that syringes were not likely to become contaminated during routine injections by this method as long as care was taken always to boil the needles.

Before syringe transmission was incriminated in respect of intravenous injections there had been several published cases where jaundice had followed administration by the intramuscular route. Hartfall *et al.* (1937) reported hepatitis following the use of gold salts. Kulchar *et al.*⁶ described 120 cases following bismuth therapy, and penicillin injections were themselves held responsible in 47 cases by Howells *et al.*⁷ in 1946, and 26 others were more recently collected by Hughes.⁸ By the present time most venereologists can recall seeing one or several such cases. And now Hughes⁹ has shown that with the intramuscular technique syringe contamination is far from infrequent but there seems to be a little reluctance in accepting the obvious implications of this modern version of the asepsis-antiseptis controversy.

The only point at which there is agreement with "EX-RAMC" is when he writes "It is hard to see why an injection of penicillin would be more likely to contaminate a syringe than one of T.A.B. tetanus toxoid or any of the other routine injections"—I am etc.

Man in Relation to His Environment

SIR—With reference to the letter on "Man in Relation to his Environment," by Dr Frank Marsh (Nov 9, p 710), and the report of the British-Swiss Medical Conference (Sept. 28, p 471), perhaps the experiences and conclusions of one who has lived for very many years in hot climates may be of interest. That experience has been a very long and varied one, in the hot back blocks of New South Wales, thirty years in India and Assam, three years in Mesopotamia and a considerable time in South America. Five years at sea have given him an insight into ships engine-rooms and stokeholds.

In studying the question of ventilation of spaces, rooms, buildings, and the effects on the human body, three factors must be constantly borne in mind: temperature, saturation, and movement of the air. Of these, temperature is by far the least important. The human body can adapt itself to very large variations of temperature provided the other two factors are favourable. Cold, if the air is still and dry, as in Switzerland, is hardly felt. In a blizzard death will occur rapidly if there is no protection. Very high temperatures can be borne if the air is dry and moving. In regulating the loss of heat from the body the skin surface is in man the most important factor. The experiment has been tried with a man exposed to a vitiated atmosphere of keeping the body in that atmosphere and allowing the head to be in the air through a rubber dam. Under these circumstances there is little improvement in his sensations. Reverse the process, body in fresh air, head still in the bad atmosphere, and relief is rapid. A place is spoken of as bracing when the air there is dry and moving, relaxing when the opposite conditions prevail, and this irrespective of the temperature. The Iraqi deserts are bracing if the cardinal conditions are observed: keep away from water, keep away from trees and keep away from buildings and streets. When new units came to Mesopotamia, the tendency was to camp in the shady date groves along the banks of the rivers. Part of the duties of the writer was to chase them out of this into the open desert. He was met with strong expostulations and it had to be explained why they would keep fitter in a dry and moving air in contradistinction to a still and moist one.

In all his residence in hot climates the writer has never seen or heard of an authentic case of sunstroke, insolation, or collapse through direct action of the sun's rays, though heat stroke and sunstroke are commonly confounded. Instances may be cited which bear out what has been said above. At one time in Bagdad during the 1914-18 war there were a very large number of cases of heat stroke with a very high mortality. Sir William Willcox came out to investigate. He asked how the cases were being treated and was shown a beautifully cool underground cellar such as is common in Iraqi houses. There the cases were taken and splashed and bathed with cold water. What could be better than to treat such cases in the cool cellar? But Sir William thought otherwise. He said take them out into the open with improvised shade where there is a breeze, and then use your cold water and electric fans if available. The cases began to recover. In the cellar the temperature was low, but the air was still and damp from the breathing of the staff and the water used. Again, in the attack on the Malakand, troops had to be sent in a forced march from Durgai. Capt Wooley, I.M.S., in medical charge, related that while the men marched through the heat of the day they were perfectly fit. During the much cooler night, when they passed through a deep rocky gorge where there was little perfusion of air, the men went down like ninepins.

One very important point must be remembered. In a dry hot moving air the loss of water from the body through invisible perspiration is very large, and large quantities of salt are washed out of the blood—it may be with serious results. In the stokehold this is frequently seen as "fireman's cramp." Give such a sufferer a long drink of salt and water, which he laps down with the greatest gusto, and his cramps rapidly disappear. Intravenous injections of hypertonic saline have been used as an aid to the treatment of heat stroke. Dief in hot climates requires consideration. In cold climates a large number of calories are used in keeping up the body heat. The amount eaten is largely a matter of habit and those coming to the Tropics are inclined to eat as much as they did in a cooler climate. Another point which affects health in the Tropics

is housing. Masonry houses must be of good size, with large and airy rooms and good verandas. Most European houses conform to this standard. It is otherwise with most of the Indian-masonry dwellings. The rooms tend to be cellular and ill-ventilated, and in many cases the houses are too small—I am, etc.,

Taynult Argyll

P F CHAPMAN

Unemployed Specialists

SIR—Hospitals all over the country are being asked to consider the employment of full-time specialists at salaries of £1 000 per annum, and the Minister of Health has intimated that the Treasury will be willing to meet the cost of these salaries if the hospitals are unable to do so from their funds. Several points arise from a consideration of this scheme. It seems grossly unfair that specialists should have this preferential treatment over doctors who are desirous of entering general practice. It may be said that provision was made for them under the rehabilitation scheme, but this scheme was also available to specialists if they so desired. There must be many hundreds of doctors who would be only too glad of a subsidy of £1,000 for their first year in practice, and there seems no legitimate reason why they also should not be given a grant. It has been said that the specialist will suffer greatly owing to the difficulty in getting established before the coming of the National Health Service and that if something is not done he will be lost as a specialist. This is illogical, as presumably every doctor will be included in the Service, and if a doctor holds specialist qualifications I cannot believe that he will suffer by reason of having done other work in the meantime.

There are many doctors who were discharged from the Services on health grounds long before any provision for rehabilitation was made. Many of these must have suffered considerable hardship, and I have personal knowledge of one case in which neither the BMA nor any other body would give help even in the nature of a short term loan where a doctor's health had been so impaired as to render him unable to insure his life.

This 'spoon feeding' is nothing short of deplorable, is being played into the hands of the Minister of Health, with whom we are still in disagreement, and to those who accept it nothing short of charity or unemployment pay—call it what you will. And all this at a time when there is plenty of work to be done. It is to be hoped that the young men now out of the Services will put their backs into the job, and even if the job is not quite what they would wish do it with a will and do away with any sense of weakness and dependency either on the State or their fellow men—I am, etc.

Sonning

J J DAVIS

Colonial Medical Service

SIR—Further to your correspondent 'West Africa' (Dec 21 1946 p 963), may I after nearly four years' service on the Coast add a few points. Like 'West Africa' in his early days I have been encouraging medical friends to consider the Colonial Service, but with the new salary scale suggested by the Harragin Commission I shall hold my tongue.

Even since 1943 the cost of living has risen considerably and, as 'West Africa' points out, will rise even further. For example, my cook gets and needs 75% more than when I took him over from another European who was leaving the country in 1943. Market prices are, theoretically, controlled in so far as fruit, fish, meat and one or two other items are concerned but a very skilful 'fleece-the-white-man campaign' makes a mockery of the control. Household goods and basic foodstuffs imported from the United Kingdom are all more expensive than at home. Glassware, china and other breakables suffer from constant packing and unpacking as well as from 'boys'. Linen and clothing generally suffer from the effects of a tropical climate. Replacements of all kinds therefore are heavier than would be the case in England. The necessity of providing a second home in England for a wife and children is an additional expense which must be considered in assessing the value of incomes applicable to tropical service.

To offer a man in these days £660 with the possibility of rising to £1 200 may attract unmarried adventurers for a short time but will not retain the services of many men with a family or

other commitments to consider. As a result of the Commission's report I will gain financially in the immediate future. In view however, of the whole trend of policy in the past as referred to by 'West Africa' and one's older colleagues, I view my future in the Service with some apprehension. In consequence, much as I enjoy the type of life and the work and the friendly relationships existing in the department I for one will leave the Service if the Commission's recommendations are adopted—I am, etc.

'THIRTY

The Unstable Adolescent Girl

SIR—In her letter (Jan 4, p 30) on the subject of the unstable adolescent girl Dr Muriel Barton Hall gives I.Q.s as criteria for the diagnosis of degrees of mental deficiency, names mental defectives, moral defectives, and social defectives as separate entities, then criticizes the appendix to the report of the Committee on Psychiatry and the Law for offering no explanation as to which cases may be dealt with under the Mental Deficiency Acts. Surely the answer is mental defectives, and the definitions in the Act are quite clear. Mental deficiency is defined as a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by diseases or injury. It should be noted that the deficiency is of *mind*, not of that particular aspect of mind which enables a patient to say why it is foolish for Bill Jones to put his trousers on over his head.

It follows that any type of mental inadequacy necessitating care and supervision can properly be dealt with under the M.D. Acts provided the inadequacy is due to inherent causes or was induced by disease or injury before the age of 18 years. Under the M.D. Acts machinery already exists for the care and treatment of a large proportion of unstable adolescent girls, including those unnecessarily labelled psychopaths. While no one would wish to deny the value of mental tests when properly used, a little healthy debunking of the I.Q. may serve to clear the air and stimulate the utilization of the machinery already in existence—I am, etc.,

St Albans Heris

C GUY MILLMAN

Medico-Legal

A STERILIZED HUSBAND

Before the passage of Herbert's Act—The Matrimonial Causes Act 1937—wilful refusal to consummate a marriage was not a ground for proceedings in either divorce or nullity. That Act, however, laid down that a marriage should be voidable on the ground that it had not been consummated owing to the wilful refusal of the respondent. In *Cowen v Cowen* (1945) the Court of Appeal gave a wife a decree of nullity where her husband had either insisted on using a contraceptive or had practised coitus interruptus, so that he intentionally frustrated conception, one of the principal ends of marriage. The concept of wilful refusal has now been still further widened.

In *J v J* a husband, just before the marriage, had himself sterilized by vasectomy, telling the doctor who performed the operation that he desired it because there was insanity in the wife's family. Mr Justice Jones found that this act amounted to wilful refusal to consummate the marriage. He rejected the wife's petition, however, on the ground of her acquiescence. Apparently the doctor who performed the operation had insisted that both parties should sign a statement declaring that they fully understood and realized that the operation while likely to improve general conditions of health and function produced total and irremediable sterilization. This statement was produced in court. The wife gave evidence that she had signed it on the husband's promise not to have the operation until after they were married, but admitted that she knew of the operation before the marriage. The judge therefore held her to have acquiesced, and ruled that it would be inequitable and contrary to public policy to grant her a decree.

Obituary

SIR HENRY MARTYN, KCVO, FRCS

We record with regret the death on Jan. 7 of Sir Henry Martyn, lately surgeon apothecary to H.M. Household at Windsor. Henry Linnington Martyn was born in London in 1888, the son of Henry Matthews Martyn of Broadelyst, Devonshire and was educated at King's College School, Wimbledon and at King's College Hospital, where he gained three open scholarships in the University of London intermediate examination in anatomy, physiology, and pharmacology in 1908. Two years later he won the senior scholarship and qualified MRCS, LRCP, and in 1911 took the degree of MB, BS with honours in medicine, surgery, and forensic medicine, winning the university gold medal. He was elected FRCS in 1913. Martyn held the posts of house surgeon and house surgeon to the aural department at King's College Hospital in 1911. He was resident medical officer at the King Edward VII Hospital, Windsor, in the following year, and clinical assistant at King's College Hospital in 1913. During the war of 1914-18 he held a temporary commission in the R.A.M.C., serving successively as second surgeon and registrar to No. 12 General Hospital, surgeon to the Princess Christian Military Hospital, and surgical specialist to No. 10 General Hospital. In January 1919, he was invalided out as a result of sickness contracted on active service.

On return to civilian life Martyn settled in practice at Windsor and became surgeon, later consulting surgeon to the ear, nose, and throat department of the King Edward VII Hospital. In 1936 he was appointed surgeon apothecary to H.M. Household at Windsor, a position he held until 1938, when he was succeeded by Dr E. C. Malden. He was also consulting aural surgeon to the Maidenhead Hospital, the Staines Chalfont Windlesham, and Iwer Cottage Hospitals, the Staines Joint Fever Hospital and Cippenham Fever Hospital. His contributions to medical literature included notes on the treatment of septic wounds in a base hospital (*Journal of the R.A.M.C.* 1915) and on the operative treatment of septic meningitis (*Lancet* 1923). Martyn was in attendance when the late King George V suffered from bronchitis in 1931 and he also signed the official bulletins during the late King's illness in 1929. In 1923 he was appointed M.V.O. He became C.V.O. in 1927 and four years later was created KCVO for his services to King George V.

JOHN H. WEST MRCS LRCP DA

The news of the death of Dr. John Hardstaff West at Hill End Hospital, St. Albans, on Dec. 25, will come as a great shock to his many friends and colleagues at Barts and in Cardiff. John West qualified at St. Bartholomew's Hospital in 1932 and after holding various junior hospital appointments became senior resident anaesthetist at Barts. After holding this position for some years he went to Cardiff as lecturer in anaesthetics to the Welsh Medical School. He served in the R.A.M.C. during the war years. Dr. John West was an outstanding anaesthetist and was respected and liked by both colleagues and patients. Many of his former students will remember with gratitude his patient instruction and his pleasant personality. Among all his many friends and acquaintances there was no one who did not speak of him with affection. His last illness was borne with the courage and cheerfulness so characteristic of him.

A former colleague writes: Recently saddened by his impending departure from among us, the friends and colleagues of John Hardstaff West will be doubly distressed at the news of his death from acute illness on the eve of his setting out for Nairobi. Ten years ago he had come to Cardiff from Barts with the highest recommendations—which we soon found were no overstatements—of his charm as a colleague and his excellence as an anaesthetist. As a lecturer in his subject in the Medical School and as anaesthetist to the local teaching hospitals he was much in demand. His work was outstanding and he was the only anaesthetist in the town engaged

solely in the practice of anaesthetics. As such he succeeded Gordon Greaves who was killed in a motor-car accident in 1936. Early in the war a strong case was made for keeping him in this country but Johnny West was not of the type to remain long away from a fighting front. One day when examining in London, I was not surprised to receive a visit from him in uniform—to say goodbye on his way abroad. As a major in the R.A.M.C. he was for a time in Kenya. He and his wife, who was also in the R.A.M.C., were married in the cathedral at Nairobi, and they were much attracted to the country. It was not perhaps surprising that after his demobilization and his return to Cardiff we noticed that he was somewhat restless. He soon announced his departure for Nairobi, where he had been invited to become anaesthetist to the hospital and lecturer in the medical school. This was sad news indeed to those of us who valued his friendship and had come to depend on him and his work. He was always quiet, cheerful, and kind. I have never seen him angry or put out in any way, and his benevolent smiling eyes gazing through large glasses gave the utmost confidence to his patients as well as to those of us who knew him and the high standard of his work. Johnny West, as his friends called him, was beloved by all. Our sympathy must go to Mrs. West and to his parents, but for him what Lord Grey wrote of his nephew is very applicable, 'I do not feel that we ought to be sorry for Adrian, if the object of life is to live without reproach to become a fine character and to act nobly, then Adrian's life has been a complete success'—L. C. R.

C. GRANT PUGH M.D.

Charles Grant Pugh, for thirty-two years medical officer of health at Southend-on-Sea, died on Dec. 19, 1946. Of mixed Scottish and Welsh descent he came of a family with a decided medical bent for his elder brother, the late William Thomas Gordon Pugh, was for many years medical superintendent of Queen Mary's Hospital for Children at Carshalton and his sister was before her retirement, a senior member of the London County Council nursing staff. His surviving brother is a dental surgeon in practice in Streatham.

Charles Pugh was educated first at Aberystwyth and then at the Middlesex Hospital, where in 1898 he was Senior Broderip scholar and Murray scholar. He graduated MB, BS with honours in medicine in 1899, proceeded M.D. in 1900, when he was gold medallist, and two years later took the Cambridge D.P.H. It was characteristic of Pugh that he selected his medical school for the reason that the house appointments there were made on the examination results. He would doubtless have been a consultant physician had not the particular circumstances of the Middlesex Hospital made it likely that a considerable time would elapse before he could expect promotion to the honorary staff. After some fruitful years of service on the Metropolitan Asylum Board and experience as deputy medical superintendent at Bethnal Green, he was for some time with Dr. J. C. Thresh, then in Chelmsford, Essex, finding in him a formative influence of the first importance.

At Southend he was appointed M.O.H. in 1908, and there he found ample scope for his all-round talents, both as physician and as administrator. In those days when the area was less well served by consultants than it is at the present time, his opinion was frequently sought by his general practitioner colleagues in difficult medical cases. The health services of this rapidly growing population were developed on him on sound lines until the outbreak of the first world war temporarily interrupted his programme. After serving in the Balkans with the rank of captain R.A.M.C., he returned to Southend, where he was foremost in calling attention to the urgent need for better hospital provision. Within a few years the generosity of Lord Iveagh and a spirited local initiative resulted in the creation of the New Southend General Hospital.

The Local Government Act of 1929 afforded a great opportunity, of which, on Pugh's advice, the corporation took full advantage. The sick wards of the Poor Law Institution at Rochford were transferred from the Board of Guardians and appropriated for hospital purposes and when the extensions begun by the guardians were complete Pugh set himself to the great task of modernizing the hospital. In 1940, a few weeks before his retirement, he had the satisfaction of seeing

completion, at a cost of £400,000, of new buildings of the most modern design

Pugh's was an arresting figure in any company. Distinguished in appearance, courtly in manner, and deadly in argument, there were few gatherings which he failed to dominate through sheer personality. In him his committees invariably found a shrewd, far-sighted, and courageous adviser. To his staff he set an example of all that is best in the public service, and with his professional colleagues he was invariably helpful, considerate, and popular. Pugh was instinctively liked and trusted by children and some of his happiest hours were spent in their company in the wards of his infectious diseases hospital. His own clinical knowledge discerned clearly the nature and progress of the malady which was to cause his death and he faced the inevitable end with all the stoic courage and lack of complaint which were characteristic of the man. His staff retained their affectionate admiration for him, undimmed by his absence in retirement and his passing is felt acutely by all who knew and worked with him.

SIR WILLIAM COLLINS K C V O , M D , M S , F R C S

A correspondent writes: One could scarcely think of Sir William Collins without reference to the brilliance of mind which adorned his person. To that brilliance his scholastic attainments testify, but alone they might present a picture of one whose interests were purely academic. To a superficial observer his natural dignity and reserve might even have given such an impression which would be quite untrue. A habit of philosophy and practice in medicine are humanizing influences. Added to a depth of kindness and understanding of the problems of life, they moulded a great man whose gifts were used in the service of others in public and in private relationships. His conversation which he illuminated with his own interest made one realize how wide were his sympathies and his friendships. Among his medical and nursing interests district nursing owes him much, for he was deeply concerned that the benefits of home nursing should be available without cost to all who needed that trained skill and comfort. As chairman of the Central Council for District Nursing in London for over thirty years and later as president, an office which he held until his death, he was able to advise out of a wide professional experience, a profound knowledge of affairs, and a liberal and statesmanlike habit of mind which made him a generous opponent. In discussion one might momentarily disagree and later realize that he had only more quickly reached the fundamental truth. Thus one learned to rely on him to a degree that makes the loss of his counsel the greater, even if it were possible to fill the place in mind and heart of one who so combined human wisdom and kindness.

J J THOMSON, O B E , M D

Dr John James Thomson, who died on Nov 18 1946, was born in Lanark in 1883. He completed a five-year apprenticeship in engineering in Edinburgh before he turned to medicine. He was awarded the Beaney prize for anatomy and surgery and graduated M B , Ch B with first-class honours in 1908. After a short period in general practice and as a ship surgeon he emigrated to Canada, and was for a time in practice in Vancouver City and also on Vancouver Island. He was later tuberculosis officer for Vancouver City. He was married in 1912, and in 1914 he entered the Royal Canadian Army Medical Corps and served in France and Gallipoli. As Major Thomson he was then for a long time at the 10th Canadian General Hospital at Brighton, and was awarded the O B E for his services there. On being demobilized he remained in England and was appointed tuberculosis officer for the West Riding of Yorkshire. In 1921 he became tuberculosis officer for the North Riding and continued in this position until ill-health enforced his retirement in August, 1946. He published papers on the early diagnosis of pulmonary tuberculosis and on the immunization of cattle against tuberculosis. He is survived by two sons.

A correspondent writes: Dr Thomson's outstanding characteristics were his devotion to his work and his complete selflessness. He was a man of profound intellect, but he had no ambition for himself, and preferred that the good

work he did should be kept hidden. He was interested in many subjects—more especially genetics, stockbreeding, philosophy, theology, geology and music.

We announce with regret the death on Dec 6 at his home in Dorset, of JOHN LAWRENCE GRAHAM-JONES. Born in 1881 he was the eldest son of the Rev C E and Mrs Graham Jones and was educated at Magdalen College School, Emmanuel College, Cambridge, and at St Thomas's Hospital. As a young man he saw active service in the South African War as a trooper in the Imperial Yeomanry. He qualified M R C S , L R C P in 1908, graduating M B , B Ch at Cambridge in 1910. After various residential appointments at St Thomas's he entered into private practice at Guildford with the late Mr Branson Butler. Then his bent towards surgery found expression in the 1914-18 war when he served as surgical specialist in France and later in association with his friend G R Girdlestone at the Ministry of Pensions Orthopaedic Hospital, Oxford. After five years in Oxford he removed to Parkstone, Dorset, and was appointed honorary surgeon to the Cornelia and East Dorset Hospital, Poole. In 1933 he retired from practice, and settled in the country near Dorchester. But it was not a life of sheltered ease that he sought, for his activities continued unabated and his liking for a country life gained added scope. He had a deep sense of public duty and gave much time and thought to educational and parochial matters. He was one of the governors of Dorchester Grammar School until 1945. During the late war he became chairman of the Ministry of Labour and National Service Medical Board for Weymouth and Dorchester.

F B writes: It was the happy circumstances of his own son's friendship for my two boys at their preparatory school that introduced me to 'G-J' on my settling again in England after some years of practice abroad. I became his partner, and the pleasant professional association ripened into a permanent friendship though latterly war conditions limited our opportunities for meeting. A man of taste and culture, widely read and a musician of considerable talent, he was at the same time a first rate practitioner, and though his inclinations were largely surgical he was none the less a sound physician. His wise counsel and advice were always freely available and unselfishly given and I valued his opinion. At the Cornelia and East Dorset Hospital, Poole, he rendered devoted service clinically and in committee, ably supporting every measure designed to enhance efficiency. He was medical officer to several residential schools and was especially sympathetic and successful in his care and treatment of children as likewise of the aged. He was not only doctor but also friend and adviser to many. Combined with high professional attainments he had a love of outdoor pursuits. His family life was ideally happy, and the sympathy of a wide circle of friends and colleagues will be extended to Mrs Graham-Jones and their son and daughter.

DR GEORGE FOGGIN of Newcastle, who died on Christmas Day had spent almost his entire professional life in the school medical service. He qualified at Edinburgh in 1890 and from that time onwards his main interests were in ophthalmology and paediatrics. He became ophthalmic surgeon to the Royal Victoria School for the Blind and was for some years assistant surgeon at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye. He was the author of several papers on the prevention of early blindness and on errors of refraction in school children. As long ago as 1894 as a member of the old School Board, he was chairman of the Special Cases Subcommittee of Newcastle upon Tyne which afterwards became known as the Children's Care Subcommittee. His appointment as school medical officer to the Newcastle Corporation was one of the first of its kind, and in 1902 it carried with it a salary of £125 a year. His connexion with the Eye Infirmary allowed him to arrange for the sight testing of school children some years before this became usual in other parts of the country. Dr Foggin had almost forty-three years' service as a school medical officer, and his death has come less than a year after his retirement at the age of 85. He had been responsible for opening one of the early central kitchens for feeding school-children in 1908, and right up to his retirement he maintained his interest in all aspects of the care of school children and in their nutrition.

DR HARRY MCENTEE died suddenly in his own surgery on Dec 29. Patrick Henry Maurice Clifford McEntee qualified in Dublin in 1926 at the age of 29. He had been in general practice at Whalley Range, Manchester, for many years and had overworked steadily through the war years. He acted as a member of one of the local medical boards during the war and was extremely popular with the patients in his large practice. He is survived by his widow and four children.

Universities and Colleges

UNIVERSITY OF LONDON

The following candidates have been approved at the examination held

AD—Branch I (Medicine) R A J Asher R D Blachford A Bloom
A C Cochran I S Dalton N H Desai R G Evans W Fine R A Henson
E Joles P D C Kimmont D C Lewin R I McCallum A T M Roberts
Stafford Clark P H Sutton Branch II (Pathology) K R Hill C C S Pike
Branch III (Psychological Medicine) B M C Gilsenan Branch IV (Midwifery
(Diseases of Women) G H Bancroft Livingston Jean R C Burton Brown
J Medal D A Davies P S Jaikaran Muriel G Rose Branch V (Hygiene)
J Plydell T D Spencer S J Sutton Branch VI (Tropical Medicine)
W Hinds O N Ransford

A course of four public lectures on Some Aspects of Pharmacological Chemistry will be delivered by Dr F Bergel on Tuesdays Jan 21, Feb 4, Feb 18, and March 4, at 5.15 p.m., in the Physiology Theatre, Gower Street W.C.

UNIVERSITY OF DURHAM

A congregation held on Dec 20 1946, the following medical degrees were conferred

M.B. B.S.—Irene O Blankley A Ross *Diana L Priest *P Wise
* In absentia

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council of the College held on Jan 9 with Sir Alfred Webb Johnson, Bt., President in the chair, the Honorary Fellowship was conferred on Dr Louis Bazy formerly resident of the Académie de Chirurgie, and consulting surgeon to the French Army and on Dr Leopold Mayer President of the International Society of Surgery

Prof G Grey Turner was appointed honorary curator of the instrument collection in the College. It was reported that Sir Alfred Webb Johnson had been elected *Associé Etranger* of the Académie de Chirurgie of Paris. It was agreed that Dr James Craigie formerly of Toronto, should give an Imperial Cancer Research Fund lecture in the College in place of Prof W E Gye

The Council reiterated its opinion that a Statutory register of specialists is neither necessary nor desirable

The Princess Beatrice Hospital London was recognized for the resident surgical post required of the candidates for the Final Fellowship examination, and the additional post of Resident Surgical Officer was recognized at the Victoria Hospital, Blackpool

A Diploma of Fellowship was granted to J G Coxon

Diplomas of Membership were granted to H Rawlings and J Redfern

A Diploma in Child Health was granted jointly with the Royal College of Physicians of London, to N F E Burrows

Diplomas in Psychological Medicine in Laryngology and Otolaryngology and in Industrial Health were granted jointly with the Royal College of Physicians of London to the following successful candidates

DIPLOMA IN PSYCHOLOGICAL MEDICINE—H S Capote Margaret T Collins
Cowan G R Debenham J Farr T C N Gibbins J R Hawkings R M M
Lunter A Kamal P W W Leach L F E Lewis D O Lloyd N J de V
Lather P R A May A R Norton G O Gorman M A Partridge Mulder J
M D Rice R A B Rorie D Rumney F T Shadforth I C P Smith
R Stallworthy K R Thomas M G Valentine G A van Someren
DIPLOMA IN LARYNGOLOGY AND OTOLARYNGOLOGY—A D Bateman P Chandra
A D Sa P R B Gimaldi A R Harper S Kavanagh D G Lloyd Davies
A McO Macreor J Magill T A Narayanan H N Perkins H C Purser
Tith S N Sarma C J Scott J B Scott E M Sewell H J M Stratton
S Walker H A Ware
DIPLOMA IN INDUSTRIAL HEALTH—A L L Silver

On April 10 the Council will elect a member of the court of examiners in the vacancy occasioned by the retirement in rotation of Mr L A Crook who is applying for re-election. Fellows of the College desirous of becoming candidates for the office must make application in writing to the assistant secretary of the College (Lincoln's Inn Fields W.C.) by Monday Feb 3

In the announcement of Dr Meave Kenny's appointment to the University Readership in Obstetrics and Gynaecology at the British Postgraduate Medical School (Jan 4 p 57) she should have been described as Miss Meave Kenny

The Services

Major Hoo Min Sein M.S. medical superintendent, Rangoon General Hospital has been appointed OBE (Civil Division)
Squad-Ldr H H S Brown R.A.F. has been awarded the Air Force Cross

The Efficiency Decoration of the Territorial Army has been conferred upon Lieut-Col (Hon Col) J A Matheson OBE R.A.M.C.

Medical News

A meeting of the Society for the Study of Addiction will be held at the Medical Society of London (11, Chandos Street, W.) on Tuesday, Jan 21 at 4 p.m., when Dr A P Rossiter Lewis will read a paper entitled 'Alcohol and Abnormal Behaviour in Head Injury Cases'

A meeting of the Middlesex County Medical Society will be held at Busch House Open Air School, Isleworth, on Tuesday Jan 21 at 3 p.m. Agenda: The special education treatment of handicapped pupils

A scientific meeting of the Association of Clinical Pathologists will be held at the National Hospital Queen Square London, W.C., on Friday and Saturday Jan 24 (at 9.45 a.m.) and 25 (at 12 noon) when papers will be read. Demonstrations will be on view from 11 a.m. on Jan 24 to 4.15 p.m. on Jan 25. A copy of the full programme may be obtained from the honorary secretary Dr W H McMenemey Royal Infirmary, Worcester

A meeting of the Royal Sanitary Institute will be held at South Shields Town Hall on Saturday, Jan 25, at 10.15 a.m., when papers will be read by Dr T Lloyd Hughes on 'The Future Public Health Responsibilities of Local Authorities' and by Lieut-Col John Reid on 'The Present Trend of Local Government Administration from an Engineer's Point of View'

The Ministry of Supply will hold a disposal sale at its depot at Ashchurch Gloucestershire on Jan 28-31 Feb 4-7, and Feb 11-14 (all dates inclusive). The sale includes a large quantity of medical equipment. Ashchurch is two miles from Tewkesbury and seven miles from Cheltenham and sale catalogues are obtainable from Bruton Knowles and Co Albion Chambers, Gloucester or from Mr G Hone, 120, High Street, Tewkesbury

Mr P H Mitchiner will deliver an address before the Medico-Chirurgical Society of St Mungo's College at Glasgow Royal Infirmary on Wednesday, Jan 29 at 7.30 p.m. His subject is 'Surgical Experiences in the Middle East'

On Jan 29 the governors of Wembley Hospital will consider a scheme whereby the hospital will be amalgamated with the Charing Cross Hospital when the latter takes over its site at Northwick Park where it intends building a teaching hospital. Investments and cash held by the Wembley Hospital, as well as private donations in future would remain for its own use

A course in diseases of the ear, nose, and throat, specially designed for paediatricians and school medical officers, will be given at Metropolitan Ear Nose and Throat Hospital, Granville Place W on Saturday and Sunday, Feb 1 and 2 from 10 a.m. to 4.30 p.m. and will include lectures and practical demonstrations. The class is limited to fifteen and applications must be made to the Fellowship of Postgraduate Medicine 1 Wimpole Street, W.1

The National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality has arranged a conference on 'Parentcraft and Homecraft' to be held at Friends House, Euston Road, NW on Thursday, Jan 30, at 10.30 a.m. The speakers will include Dr Leslie Housden, at 10.40 a.m. on the need and scope of parentcraft and Dr John D Kershaw, at 3 p.m., on the organization of parentcraft and homecraft teaching on a national basis. The fee for the conference is 7s 6d, which includes a printed copy of the proceedings. Applications for tickets should be addressed to the secretary of the association Miss M R Lovelock at 5 Tavistock Place London, W.C.1

The Westminster Diocesan Catholic Doctors Guild dinner and dance will be held at Dorchester Hotel, Thursday, Jan 30, at 7 p.m. when His Eminence Cardinal Griffin will receive the guests. Tickets (£2 2s each) can be had from the Honorary Secretary, 5 Wimpole Street W.1

Major-Gen R J Blackham CB CMG, CIE DSO M.D. has been re-elected a member of the Common Council of the Corporation of London for the twenty-second consecutive year. It was on the proposal of Gen Blackham that the Corporation of London entertained the British Medical Association to a reception at the Guildhall as part of the Association's centenary celebrations in 1932 and he was chairman of the special committee of the Corporation which arranged the reception

Lord Horder, chairman Prof Winifred Cullis vice-chairman and Mr Cyril Bibby hon secretary, have announced the formation of the Family Relations Group. At present it comprises the British Social Hygiene Council, the Central Council for Health Education the Eugenics Society, the Family Planning Association the Family Welfare Association, the Marriage Guidance Council, the National Council for Maternity and Child Welfare, and the Pioneer Health Centre

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec 28

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1946					1945 (Corresponding Week)

* Measles and whooping-cough are notifiable in Scotland and the returns are therefore an integral part of the vital statistics of Scotland and Northern Ireland

† Includes puerperal fever for England and Wales and Eire
‡ Totals for Eire notifications include those for the previous week
§ It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct 26 Nov 2 9 16, 23 30, Dec 7 14 21 and 28

EPIDEMIOLOGICAL NOTES

Infectious Diseases, 1946

A comparison of the number of notifications of infectious diseases with the preceding years is as follows

	1940	1941	1942	1943	1944	1945	1946
Scarlet fever	65 573	59 111	84 932	116 217	93 801	74 392	57 614
Whooping-cough	53 403	171 406	65 563	95 859	93 107	62 022	92 023
Diphtheria	46 683	51 091	42 318	35 944	29 446	25 059	18 186
Measles	407 908	406 507	285 300	374 198	117 437	443 002	154 761
Acute pneumonia	47 712	50 214	42 487	52 225	38 175	34 059	36 106
Cerebrospinal fever	12 791	11 129	6 089	3 380	2 883	2 691	2 697
Dysentery	2 843	6 597	7 177	7 772	10 150	16 533	8 441
Enteric (typhoid and paratyphoid)	2 824	4 703	887	707	536	679	1 367
Deaths from influenza in the 126 great towns	5 510	2 993	1 544	6 280	1 744	1 307	2 699

A further large decline in the notifications of diphtheria was recorded for 1946, despite a poor start. The 6 220 notifications in the first quarter were slightly in excess of the 6 061 for the same period of 1945. The largest relative decline was in the fourth quarter when 3,831 cases were reported as compared with 7,590 in the fourth quarter of 1945.

The notifications of scarlet fever were the lowest for the seven years reviewed. Measles and pneumonia were also less prevalent than usual. The incidence of cerebrospinal fever has apparently become stabilized at two to two and a half times the pre-war level after the epidemic in the early war years. Dysentery accounted for only half the number of cases recorded in the preceding year. There is no obvious explanation for this rapid decline and it may be due to variations in the standards of notification.

The rise in enteric fevers was partly due to an outbreak of typhoid in Aberystwyth. The increase in deaths from influenza in the 126 great towns was due to a relatively heavy incidence in the first quarter, when 2 156 deaths were registered as compared with 692 and 1,131 in the preceding first quarters. In the fourth quarter 221 deaths were returned against 395 and 317 in the same quarter of 1945 and of 1944.

Discussion of Table

In England and Wales infectious diseases were less prevalent. The decreases in notifications included measles 701, whooping cough 437, scarlet fever 258, and diphtheria 63, the only increase was acute pneumonia 61.

The largest falls in the notifications of measles were Durham 205, Northumberland 200, and Warwickshire 146. An exception to the general trend was an increase in Yorkshire North Riding 106. The incidence of whooping cough declined in most areas, the largest falls were Lancashire 65 and Yorkshire West Riding 57. A small decline in cases of scarlet fever occurred throughout the country, but the only decrease of any size was Lancashire 70.

There were 180 notifications of diphtheria—the smallest number ever recorded—the decreases during the week being Lancashire 42 (mainly in the C.B.s), Northumberland 11, and London 10. Dysentery was prevalent in only two areas—Lancashire, Preston R.D. 17, and Glamorganshire, Cardiff C.B. 14.

In Scotland decreases were recorded in the notifications of scarlet fever 31, whooping cough 85, dysentery 19, and measles 16 while a small rise occurred in the incidence of acute primary pneumonia 24.

In Northern Ireland there was a decrease of 24 in the outbreak of measles in Belfast C.B.

Week Ending January 4

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,161, whooping cough 2,030, diphtheria 242, measles 10,823, acute pneumonia 1,264, cerebrospinal fever 61, dysentery 65, paratyphoid 3, typhoid 5.

Corrections

Corrected figures for the notifications of diphtheria and measles for England and Wales were for the week ended Dec 14, diphtheria 299 and measles 6,986 (Lancaster 79 and 1,482), for the week ended Dec 21, diphtheria 263, and for the week ended Dec 28, diphtheria 180 and measles 7,068 (Stafford 6 and 184).

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Potency of Oestrogens

Q—A patient requires an oestrogen preparation for menopausal rheumatism. She is allergic to fish. She can take stilboestrol by mouth but I have always found that menopausal rheumatism requires fairly large doses of stronger preparations. Are there any of these which are not made up in cod-liver oil?

A—It is difficult to compare the potency of various oestrogens for their effects depend so much on the route of administration, esterification, the vehicle and the spacing of doses. If the implication of this question is that natural oestrogens are more powerful than the synthetic ones then it can be said that stilboestrol is two to five times more active than oestrone when both are given by mouth and the effects of stilboestrol by mouth and of oestrone by injection are about equal. Oestradiol benzoate or dipropionate in oily solution and given by injection may weight for weight be more active than stilboestrol given by mouth but any such advantage is cancelled out by the fact that stilboestrol can be given more frequently and in regular and equally spaced doses by the oral route. In practice it seems likely that 10 mg of stilboestrol by mouth three times a day is at least as effective as twice-weekly intramuscular injections of 50 mg of one of the esters of oestradiol. Moreover the dose of stilboestrol can be readily and all too easily increased. Another synthetic oestrogen dienestrol, is often stated to be even more active than stilboestrol but this has not yet been established.

In any case, however it is doubtful whether it is wise or necessary to give large doses of oestrogens to a woman at or past the menopause. Stilboestrol given at the rate of 1 mg three times a day for any length of time will almost certainly cause endometrial hyperplasia and uterine haemorrhage which may be heavy and prolonged is likely to occur during or after treatment. If the rheumatism is due to lack of oestrogen it should respond to very much smaller doses of either stilboestrol or oestrone by mouth. If large doses are employed they should be given only for an initial period of two or three weeks in order to bring the condition under control whereupon the dose should be decreased.

The nature of the oily solvent used for natural oestrogens is not usually disclosed by the makers of the various proprietary preparations. If for some special reason the use of such oily solutions is desirable the makers of any particular preparation should be approached directly for an assurance that it does not contain fish oil.

Curare and Surgical Shock

Q—Wutac and Fisher have shown that under curare alone patients found the pain of operation intolerable and welcomed the subsequent administration of cyclopropane. In other words the cerebrum is bombarded by painful stimuli arising at the site of operation. From practical experience there seems to me to be a real risk of producing surgical shock by maintaining anaesthesia at too light a level for the surgical procedure taking place. I have seen it stated that a light level of anaesthesia together with sufficient curare to produce the necessary relaxation is all that is necessary. If my reasoning is correct is this very real danger of surgical shock resulting from insufficient curare or is curare fully appreciated by anaesthetists?

A—There is no conclusive evidence that curare extracts have an anaesthetic effect in normal doses. In very large quantities they have produced unconsciousness in man. There is some evidence that they interrupt conduction across the preganglionic synapses of the autonomic nervous system. The remarkable immunity of most patients from shock in severe operations where *d*-tubocurarine chloride has been used suggests either that painful stimuli in the absence of any active reaction are of no importance in the development of operative shock or

that *d*-tubocurarine chloride has a specific protective effect comparable with that of nerve block.

Two patients were subjected to mid-thigh amputation under light first-plane anaesthesia tubarine being used to ensure quiescence in neither of these did any noticeable degree of shock develop. In my personal experience better results are obtained in abdominal operations with light anaesthesia and more tubarine than with moderately deep anaesthesia and less tubarine. In either case it seems to be important to avoid so far as possible any active reaction to surgical stimuli. It must be understood that the views expressed are purely speculative that the use of curare extracts in anaesthesia should be regarded as still in the experimental stage that deaths have occurred during its administration and that a close watch should be kept during any major operation for signs of the development of operative shock. In one prostatectomy shock did develop and there it was unexpectedly severe for the degree of surgical trauma.

Cheirpompopholyx

Q—A practising surgeon in India has a severe cheirpompopholyx affecting the ring and middle fingers of his left hand. The hands are being constantly washed in all the usual antiseptics recommended for the treatment of this condition. Carbolic lotion, surgical spirit and penicillin ointment have all failed to help. Can anything further be recommended?

A—Cheirpompopholyx may be a secondary trichophytide reaction from ringworm infection of the feet and is not commonly due to direct infection of the skin of the hands. If that is the diagnosis in this case then the fierce treatments which have been employed would have been better directed to the feet and will, in any case be likely to aggravate the pompholyx if applied to the hands.

However, the great majority of cases of pompholyx of the hands are constitutional and nervous in origin and are aggravated by heat and moisture. Tab phenobarbitone gr 1/4 (16 mg) two or three times a day by mouth and the cessation of all local treatment to the hands might be more helpful. If any local treatment is employed it should be of a bland type antiseptics and parasiticides being avoided. Dabbling the hands in saline or a weak lead lotion and the use of a calamine cream and then perhaps very small fractional doses of unfiltered x rays would help. It is clearly necessary to establish the diagnosis and to assess the patient's health and temperament in relation to his environment.

Plastic Induration of the Penis

Q—What is plastic induration of the penis? What are the current views on its aetiology and treatment?

A—Little is known about the aetiology of plastic induration of the penis or what is generally known as fibrous cavernositis. A few cases are due to some recognized local cause such as infection. But the aetiology of the primary cases is obscure. Gout, diabetes and rheumatism are sometimes mentioned as causes. Treatment is unsatisfactory but usually after progressing for a time the trouble becomes stationary. I have seen cases improved by the application of small doses of radium. Recently Lowsley has again advocated operative treatment. This involves dissecting away the fibrous tissue which has formed on the dorsum of the penis between the two corpora cavernosa. As this trouble usually affects middle-aged men and never interferes with micturition operation is required only in exceptional cases.

Legal Duration of Pregnancy

Q—What are the current views as to the maximum legal duration of pregnancy?

A—There is no legal maximum or minimum duration of pregnancy. Some countries have statutory limits but we have none and when the point is raised our Courts hear medical evidence which often includes the quotation of textbooks. A very interesting case in which the possible minimum was considered was *Clark v. Clark* (Journal 1939, 1 647). Dr D. J. A. Kerr (*Forensic Medicine* 4th edition p. 173) quotes a case in which the Court accepted a gestation period of 331 days. The practice of the Court is not to be bound by any hard and fast

rule but to take all the facts into account. I know of no reported case in which the Court has decided merely on the alleged length of pregnancy that the child was illegitimate.

Grittiness in the Eye

Q—What is the cause of the common ocular symptom of grittiness in the eye? A characteristic feature of this condition is that it is worse on waking.

A—There is no clear answer to this question. There are probably a number of different causes that can produce the sensation of grittiness in the eye. A not uncommon cause is the presence of small calcareous granules in the conjunctiva. These are fairly easily levered out by means of the sharp point of a cataract knife. The characteristic feature mentioned—that it is worse on waking—rather suggests that the symptom may arise from an excessive concentration of the solid contents of tears. This raises the complicated issue of minor metabolic disturbances. As an empirical measure your correspondent may find it worth while trying the effect of diuretics.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Postgraduate Education for Medical Officers released from the Forces

Income Tax Liability

A question and reply in a recent issue of the *Journal* (Dec 28, p 1012) have aroused considerable interest, and a note clarifying the questions involved may help readers who are receiving payments under the Government scheme for postgraduate education to understand their position. There is a broad, and in theory at least a fairly clear distinction to be drawn between a Government grant to enable the recipient to continue his professional training and a Government payment to facilitate such training by enabling the trainee to take up professional duties in such circumstances as will give him suitable opportunities for the further studies. In the actual working out of such schemes the sharp edge of the distinction becomes blurred, the recipient of, for instance, a training grant paid by the Ministry of Labour usually finds it very desirable and often necessary to do practical work which has an objective value and the individual who holds a 'post and receives a salary' may find his duties to be so light that the post is in effect a sinecure. But where income tax liability is concerned the fundamental distinction holds good. If the individual receives a training grant the conditions of which do not require him to perform duties it is apparently accepted that the grant is not taxable income in his hands, if on the other hand, the individual holds an employment or office of profit, then any sums receivable by virtue of that position are liable to tax.

The scheme for postgraduate education for medical officers is set out in a Ministry of Health circular (P.G. 5 (MED) R) in which a distinction is drawn between "vacancies in existing establishments" and vacancies arising from the creation of additional posts. The position of medical officers filling the former class of post is quite clear: they are liable to perform and in fact do perform, certain duties; they hold offices of profit and their salaries are taxable in the ordinary way. The second class is perhaps less clear. In those cases it may be that some individuals are fulfilling a merely nominal roll as medical officers and, whether or not they are liable to render services to the hospital to which they are attached, are in fact doing no more than they would feel it necessary to do in an unrestricted course of study and that the payment received is therefore a 'subsistence allowance' and not a salary. Such cases may be open to doubt, but it seems not unlikely that a Court would regard them as offices of profit, however small the actual service requirements might prove to be. Indeed there is something Gilbertian in the alternative—namely that because no work is required the office ceases to be one of profit. Taking the matter a step further, however, if a man who is attached to a hospital under this scheme and is paid accordingly is not legally under obligation to perform any duties, it would seem to follow that the element of employment does not enter into the matter, and in such a case the recipient might well have a claim to be regarded in the same light as a recipient of a Ministry of Labour grant. From one or two letters we have received on this matter, it appears that the writers regard themselves as under no obligation to perform services in the hospitals to which they are attached—or at most only negligible services—and the brief reply to the inquiry referred to above may have led to misunderstanding on the part of others who occupy a less abnormal position in the scheme.

Letters and Notes

Time Marches On

Dr J. B. SIMSON (Romford) writes: Having recently reread Sir John Simon's admirable work, *English Sanitary Institutions* I have from certain passages been endeavouring to draw an analogy between the proposed conditions of service for general practitioners under the National Health Service Act and the conditions of our "colleagues" that prevailed in ancient Rome. Apparently Julius Caesar and the earlier emperors encouraged the practice of medicine by granting to those who practised certain privileges—namely the status of citizen and exemption from certain ordinary civil obligations until in time such largesse was no longer required and practitioners existed in such excessive numbers that 'the less employed among them were willing to lend a hand to the next door function of corpse bearing at funerals, or would even (more remotely from their profession) be ready to officiate as gladiators. Such being the overcrowdedness of the profession, Antoninus Pius found it prudent to restrict to a certain number of practitioners in each centre the immunities which had been so lavishly granted and from the date of his law the medical immunity from local burdens might not be held by more than five practitioners in small cities, nor more than ten in even the largest. While also, in general, the immunity could not be claimed by practitioners migrating into new districts. When the number of immunes was limited by law certain public duties were made to accompany the privilege and later it was enacted that grants of privilege should be made on local responsibility and the responsibility was assigned as the law expresses it, that they who were most interested would make sure of the probity and skill of the persons to whom they had to entrust their own and their children's lives.' At a comparatively late period in the city of Rome it was enacted that a local medical officer who 'knowing himself to be paid by salary for attending to the poor, must think of them rather than of the rich and who where there is a question of fees must take as his standard not what men fearing for their lives will promise but what men recovering from sickness will offer, and when a vacancy occurred among these officers, the filling of it was not to be by favour or on solicitation of magnates, but the remaining district officers are to propose a man who shall be worthy of their ranks and of the dignity of the office and of the emperor's approval.' Time indeed marches on.

Animal and Human Influenza

Dr J. N. McINTOSH (Stonetown, Glos.) writes: In the *Journal* of March 16 1935 (p 570), you kindly published an article from me under Letters Notes etc. entitled 'Influenza Epidemiology and Prophylaxis' in which I pointed out *inter alia* that whenever "human influenza" occurred human influenza followed. From reports there is now occurring in this country influenza in horses and cats of an epidemic nature. Are these cases notified to the public health authorities? If not could something be done about it by the Ministry of Health? If my theory is correct it appears that with our present deficiency in fats and proper foods the stage is all set for a human influenza epidemic of even greater proportions than that of 1918-19.

Medical Art Society

The Medical Art Society is to be revived, and it is hoped to hold an exhibition of members' works in the summer. Doctors who do painting or sketching work are invited to communicate with the secretary, Dr Henry Wilson, 142 Harley Street, London, W1.

Correction

Dr S. LIPETZ writes: The words 'the enabling Bill demanded by Dr. Dain' in my letter in the *Journal* of Jan. 4 (p 30) should read 'the amending Act demanded by Dr. Dain'.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: ANTHOLARY. Western London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* also unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1 on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: BRIMEDADS. BRIMEDADS. LONDON SATURDAY JANUARY 25 1947

THE CARE OF CHILDREN IN HOSPITAL

BY

J C SPENCE, MD, FRCP

Professor of Child Health University of Durham

The form of human institutions is predetermined as much by the age in which they are set as by the men who set them. Charles West founded the Hospital for Sick Children in Great Ormond Street in 1851. In this instance the age overcame the man. He was an obstetrician of the restless reforming type, as became the son of a nonconformist minister who was half pedagogue and half evangelist. Through his father's school, through an apprenticeship to a local apothecary through St Bartholomew's Hospital and through several Continental universities he pursued a notable academic course with serious pertinacity. Afterwards he practised midwifery in London, with a reputation and success which made him Lumleian Lecturer, Harveian Orator, and Senior Censor of this College. Near the age of 40 which is the climacteric of the reformer, he turned his energies to propagating the study of disease in childhood in lectures, books, and pamphlets. He was obsessed by the appalling ignorance in this branch of medicine. That more than one-third of the children he delivered would die before the age of 12 seemed to weigh heavily on his mind. He conceived the idea, rightly or wrongly, that the quickest remedy was to open a children's hospital which, he said, "would afford the means of instruction to students, as well as furnishing opportunities for extending the boundaries of our knowledge concerning a class of disease frequent in their occurrence, dangerous in their character, and often very obscure in their symptoms". Against much opposition he succeeded in founding his hospital, in the famous house of the famous Richard Mead, and there he worked for twenty-three years. But, as Norman Moore said of him, "the conduct of other men so rarely satisfied him that he was not a happy colleague and left both St Bartholomew's and the Hospital for Sick Children in a state of feud with other members of the staff". His remaining years were spent as is the way of such men, in brooding over medical education and in other discontents. So much for the man whose name we honour in these lectures.

The age he worked in needs little description. The mere mention of it raises pictures of self-confident men and women toiling earnestly in every field from poetry to politics. In many respects it was a great age, but it was an unfruitful time for this experiment of opening children's hospitals because the strongest interests were then flowing in other directions. In medicine they were towards sanitary reform. Elsewhere interests were centred on religious questions and on the self-discipline of character. In practical affairs the Puritan ethos was being harnessed to iron, coal, and railways in new industrial enterprises, in a prevailing atmosphere of excessively bad

taste which permitted even the dons of Oxford and Cambridge to erect architectural monstrosities. That Charles West and his colleagues achieved so much in circumstances so adverse was praiseworthy. They worked under difficulties. Their hospitals bore the impress of these difficulties, and we are still affected by them.

The chief of the adverse circumstances which beset the founding of the early children's hospital was the established authority of the adult hospitals already in existence for more than a hundred years. It inevitably followed that children's hospitals were built and arranged like the older hospitals. They inherited the same oblong wards and cheerless corridors. They imitated their methods of staffing and of nursing. They pursued their methods of research. This was a misfortune, because the needs and arrangement of children's hospitals differed then, as they differ now, from those of other hospitals. We have not yet escaped the influence of these false conceptions.

Another adverse circumstance that made the eighteenth-fifties an unfortunate period for the founding of children's hospitals was the prevailing sentimentality of the times. In this attitude of mind children's hospitals were regarded too much as refuge homes for slum children and too little as places for the scientific study of the diseases which might best be treated there and of the methods by which they might best be nursed. They suffered from an overdose of Shaftesbury and Dickens. The paramount need of the time, so far as it concerned the health of children, was a clear analysis of the facts about disease in childhood adduced by those methods of study which, from Swedenborg to Thomas Lewis, have revealed so much about the diseases of adult life. Another handicap to the scientific study of children's diseases in hospitals was the dread of admitting children because of the danger of death from cross-infection. The early children's hospitals avoided this difficulty by refusing to admit children under the age of 2, which, although a justifiable procedure at that time, was an ostrich-like policy towards study of disease in early infancy. Therein lies a partial explanation of our comparative ignorance in this most difficult and least understood branch of medicine. Charles Cameron's remark still holds true: "There is no branch of medicine in which experience is more necessary and yet more difficult to come by."

A discussion of these problems is not an academically exciting subject for a lecturer. It is difficult to raise it above the level of a pedestrian guide, but I choose it for three reasons. The first is its practical importance at a time like this, when the planning of new children's hospitals is in the air and when their special needs may again be subordinated as they were a hundred years ago. The second reason is that the problems involved are particular and technical, and I wish to suggest that they cannot

* The Charles West Lecture delivered at the Royal College of Physicians London on Nov. 19 1946

understood unless the facts are carefully analysed. The third reason is that during the past two years, as a member of the Curtis Committee, I have had the opportunity of examining many kinds of children's institutions, assessing their methods and comparing their results, and this experience has taught me that the care of children is as uneven in our hospitals as it is in other institutions—good in some and very bad in others, and where it is very bad the explanation lies usually in a failure to define personal responsibility, or in the imposition of a personal responsibility by a remote governing or administrative body on a staff who are unwilling to confess or complain about their difficulties.

Admission to Hospitals

The number of children's beds required in hospitals is influenced by many factors apart altogether from local variations in the incidence of disease. From my own observations I have estimated that in two children's hospitals or departments both doing the same kind of clinical work the number of beds required may vary by as much as 100%, according to the manner in which the hospital's work is carried out. A hospital with satisfactory working arrangements will deal with as many children in fifty beds as another hospital with unsatisfactory working arrangements will deal with in a hundred beds. The economics of these variations is important. Assuming that it costs £250 a year to maintain each hospital bed, which is now a modest estimate, the saving to the first hospital would be £12,500 a year, less the expenditure on the extra salaries and maintenance costs required to keep the work at a satisfactory level. If these extra costs to the first hospital be put as high as £5,000 a year it still enjoys a considerable saving. The crux of the matter is in the maintenance of satisfactory working arrangements. Therein lies true economy. I shall attempt to define these arrangements after I have examined what work is required of children's hospitals and departments.

A hospital's work is usually estimated in terms of its number of beds, its number of patients, and the average duration of their stay. The needs of a town or district are estimated by adding together these numbers from all the hospitals in the town or district. These somewhat colourless records do not take into account the variable local factors which govern hospital admissions or the standard of work within the hospitals.

We may arrive at a more precise estimate of the needs by studying figures collected by two of my colleagues, Dr Mary Taylor and Dr R. B. Thompson, who have recently made a detailed survey of all the Newcastle children who became patients within hospitals or nursing homes during the years 1943 and 1944. They undertook this research in order to find out which paediatric diseases throw the heaviest burden on the hospitals, by assessing their severity and determining their age incidence. Their detailed report will be published shortly, but I am allowed to quote some of the results which will illustrate my subject. During those two years there was little bombing in or around Newcastle, and the results can be taken as fairly representative of normal conditions. In order to assess the local variable factors and to provide comparison with results from other towns it needs to be explained that, apart from a shortage of beds in long-stay hospitals, the hospital accommodation for the city's own children was ample, and there were no waiting lists for children, that the standard of staffing was fairly satisfactory, that the citizens, considering their native caution, had a reasonable confidence in their hospitals that did not deter them from sending their children there. On the other hand, the threshold of admission was high because of a prevailing paediatric policy which

required that, whenever possible, sick children be treated in their own homes and not in hospitals, and that admission for "observation" be discouraged. An exception to this policy was the ready admission of children with scarlet fever to the fever hospital, and the low threshold of admission of children for tonsillectomy.

The inquiry covered all children in the ages between birth and the end of the twelfth year. The hospitals and nursing homes drew patients from a wide area, but only those children from the city itself are included. It was estimated that within these ages there were resident in the city 49,800 children in 1943 and 50,400 in 1944. The error of computation in these figures is such that 50,000 can be taken as average for the two years and used as a basis for calculation. The total population living within the city in these two years was estimated at 260,000. Of the 50,000 children, 3,782 were admitted to hospitals and nursing homes in 1943, and 3,704 in 1944. This is an average annual admission of 3,743 (7.48% of the 50,000 children). Of these, 890 were admitted for tonsillectomy. Excluding the tonsillectomy cases 2,853 were admitted (5.7% of the 50,000 children). Had the age groups of 13 and 14 been included, the percentage of the city's children admitted to hospitals would have been slightly lower, as the admission incidence of the older age groups is lower than in the younger age groups.

Tables I, II, and III illustrate the nature of the circumstances under which these children were admitted to hospital.

TABLE I—Types of Hospitals Admitting 3 743 Children

Children's hospitals and children's departments of general hospitals	2,163 patients
Fever hospitals	128
Children's wards in special hospitals	217
Children's sanatorium	80
Private nursing homes	95

TABLE II—Ages of Patients

Age	No of Patients	No of Patients Excluding Tonsillectomy
Under 1 year	419	418
1 year	256	252
2 years	345	312
3	338	249
4	354	235
5	372	261
6	365	237
7	310	197
8	249	166
9	227	163
10	188	136
11	176	127
12	144	100
Total	3 743	2,853

TABLE III—Admissions in Age Groups

	Total	Under Age 1	Under Age 6
Admissions including tonsillectomy	3 743	*419 (11.2%)	1 712 (45.7%)
Admissions excluding tonsillectomy	2 853	418 (14.6%)	1 466 (51.4%)

* 107 of these were treated in infectious disease hospitals

A perspective view of the various diseases for which children enter hospitals, and of the arrangements needed for their treatment, can be obtained only from a detailed analysis of many factors, including the age of the patients, the season of admission, and, in the case of trauma, the peak hours of the day when the accidents take place. I will quote only a few illustrative facts.

Table IV shows the chief categories of disease, excluding tonsillectomy patients. The distortion of statistics which comes from considering the records of one hospital only is revealed in the fact that, of 761 city children admitted to one children's hospital 552 (72.5%) were patients sent

for tonsillectomy, while of 962 children admitted to another hospital only 63 (6.5%) were sent for that purpose

TABLE IV—*Chief Categories of Disease*

	No of Patients	Remarks
Trauma	306	55 had serious burns and scalds 77 fractures and 56 head or other serious general injuries
Abscess cellulitis and skin sepsis	202	
Acute lung diseases	312	150 had pneumonia
Tuberculosis	129	3 had bone tuberculosis and 26 tuberculous meningitis miliary tuberculosis
Emergency surgery	79	31 were under the age of 3 and 42 had appendicitis
Planned surgery	115	60 were treated for hernia and 23 by orthopaedic operations
Specific infectious fevers	929	595 had scarlet fever and 190 diphtheria
Acute infective gastro-enteritis	122	
Dysentery	90	
	22	
	15	
	7	
Nephritis	11	
Coeliac disease	7	

The enumeration of patients and their diseases in Table IV reveals little of what goes on in children's hospitals. It gives no clue to the work of the staff or the arrangement of their duties. We may see the matter more clearly, however, if we examine their duties in three categories. The first is the *clinical responsibility* of doctors and nurses in the admission of each child, in its immediate diagnosis, and in its nursing care and treatment. The second is the *social responsibility*, for which I wish I could find a less tarnished phrase to describe duties which involve, amongst other cognate things, the explanation and advice given to parents at the various stages of their child's illness. The third is the *supervisory responsibility*, which devolves on one or more experienced members of the staff in controlling infections, in arranging and rearranging the right juxtaposition of patients on physical and psychological grounds, in adjusting the proportion of nurses to patients and patients to nurses, and in other duties which seem to be more important in children's hospitals than in those of adults. I shall attempt to illustrate these needs by examples, but we may get a clearer view of the picture if we attune ourselves to it by imagining in each case that the patient is our own child. I have yet to find that what is not good for our own children is likely to be good for other people's children—a useful rule of thumb in all matters concerning the care of children in hospitals.

A first example may show what is required in service and in time in the common event of a severely injured child being admitted to hospital. A severely burned child arrives in hospital within three or four hours of the accident. He will then be clad in emergency dressings and relatively comfortable. Except to those with training and experience in this branch of clinical paediatrics his condition at the time of admission will not reveal the series of sudden changes about to take place during the next twenty-four hours, each of which may need to be countered by decisive action. Within ten minutes of admission he should be seen by someone capable of assessing the injury and foreseeing the probable sequence of events. For about three hours afterwards the child will require the continuous attention of two doctors and a nurse, engaged in clinical studies of the patient's changing condition, in serial estimates of blood concentration, in intravenous plasma treatment, and in dressings under anaesthesia. For one or two days afterwards the child will require close examination at three-hourly intervals night and day to adjust the treatment to the needs of the moment. In the later stages considerable time will be spent in applying dressings under anaesthesia. Throughout all this activity the morale of

the child, on which so much will depend in the later stages of the illness, will require purposeful attention and support. The time spent in this care and treatment may be estimated in medical and nursing "man hours." During the first day of his stay in hospital a burned child may require as much as ten "medical man-hours" attention.

Other examples could be taken from children severely ill with infective enteritis or meningococcal meningitis, or peritonitis or soft-tissue injury, each of which may claim two or five medical man-hours immediately after admission to hospital. The urgency of these situations in paediatrics is due to the small margin of safety, by which delay for half an hour or a small error in treatment or nursing technique may kill the child. Only those who have worked under these conditions can appreciate the time, the concentration of effort, and the combination of clinical and laboratory skill required in the diagnosis and in the control of treatment in a busy children's department. It is easy to see how administrators, matrons, and medical men who lack that experience may fail to recognize the needs, and how dangerous it may be to leave the planning of children's hospitals in their hands. I do not wish to overpaint the picture, but from an experience spent equally in adults and children's wards it seems to me that there is no branch of medicine which requires more time, more care, more promptitude, and more experience than clinical paediatrics in hospitals.

In addition to these clinical duties the staff must find time for what I have described as their social and supervisory responsibilities. The first of these can be recognized by estimating the time spent in contacts which must be made with parents when their child is brought to hospital or taken from it. What these contacts are can best be realized if we put ourselves in the position of the parents and then see how much courtesy and explanation we would expect from someone whose judgment we trusted. The supervisory responsibility of the medical staff is exemplified in the steps which might be taken on discovering that a child's recovery had been complicated by an intercurrent infection. An examination of all the arrangements of the ward, from kitchen to napkin bins, from nurses' hands to cleaners' cupboards, might be carried out before a solution of the problem was found. The ward round comprises constant supervisory responsibilities of this kind, which claim considerable time and patience in all children's departments.

Children's Wards

It is easy to slip into satire in describing a children's ward, but the following is not far off the mark in many of our hospitals.

The room is vast. It contains twenty beds, spaced along walls tiled by Doulton or painted chocolate and yellow. The roof is remote—too remote for the cleaner's brush, and terrifyingly remote to the eyes of a child who lies many hours gazing at it. Some of the beds are three feet from the ground, to the pleasure of physicians and surgeons with ageing backs, but to the discomfort of the child who has not slept so far from the ground before. Many of these beds are protected by bars set close enough to prevent a child from lodging his head between and high enough to prevent him falling overboard. The beds stunk just a little. Near the bed is a contraption half-chair and half-locker, but it is beyond the reach of the child except by a contortion he cannot make so soon after his operation. He defeats this by concealing his personal treasures under his pillow until they are again put out of his reach. He solaces himself with comics or with paper and a scrubby pencil which he cannot sharpen.

He dislikes the pallid immobile child in the next bed because he is too young for companionship and too ill for talk, but, as is the way of children, he makes the best of it, and carries

on a conversation with a boy of his own age ten yards away over the heads of a whimpering baby and a plaintive 2 year-old standing behind the bars of his cot clad in a shapeless night-gown with a loose napkin sunk to his ankles below. This young child's plaint is not difficult to interpret. He draws the attention of a nurse busy with noughts and crosses on a temperature chart. She acts quickly, and then goes to other duties in the kitchen, where she floats mashed potatoes on plates of liquid mince. The children await their dinner but are distracted by strange events. A white coated young man arrives and descends upon the silent occupant of a bed who, knowing that her penicillin hour is at hand, breaks her silence in a four-hourly scream. There are other distractions at other times—the daily or twice-weekly promenade of an older man in black with a retinue of followers, the occasional quick incursion of a younger man more sprucely clad, who pronounces his decision with a 'put him on the list for next Tuesday,' the solemn visit of the matron, who passes from bed to bed with the same question on her lips at every bed, the arrival of an injured child at night, the piece of chocolate after dinner, the excitement of strange instruments which the doctors and nurses use but do not explain. Night comes on but there is no bedtime story, no last moment of intimacy, no friendly cuddle before sleep. The nurse is too busy for that, busy with the noughts and crosses. This daily rhythm of anxiety, wonder, apprehension and sleep is better than it sounds, because it is made tolerable by the extraordinary resilience and gaiety of the children at every opportunity. Their cheerfulness keeps on breaking through. But it is a deceptive cheerfulness.

In the hospital there are other wards like this with a kitchen, a side-room, a linen cupboard, and an entrance corridor beyond which parents shall not pass. They have no treatment room, no laboratory, no accommodation for parents, no interviewing room. Each ward is under one black-coated man of authority who, although devoted to his work, must delegate much of it to a white coated resident. He has little time for companionship with his colleagues except in committee rooms. His ward is his domain. If he is a surgeon it is a surgical ward. If he is a physician it is a medical ward.

Not all hospitals are like this. Some are better, but many others are worse, mainly because most of the clinical work is in the hands of people untrained in paediatrics or in the hospital-care of children. But I have drawn this picture in order to make concrete suggestions for its improvement.

Suggested Improvements

1 The clinical unit should be big enough to carry a trained staff sufficient in numbers for its varied duties, and working closely enough for the cross fertilization of each other's minds in daily contact over their patients. For this purpose the unit should contain not less than fifty and not more than a hundred beds, which will be subdivided into smaller nursing charges.

2 The unit should be constructed not as isolated medical and surgical wards but as a combined clinical unit carrying both medical and surgical patients, in which paediatric physicians, surgeons, and specialists combine in their clinical work. In this combined clinical unit the children are placed in rooms or wards on grounds of their age, their temperament and the nature of their illness not divided into "medical" or "surgical" cases according to their need for operations. I shall return to this theme and its many advantages to patients, to nurses, to residents, and to medical staff. Having worked under this arrangement for many years, I and my colleagues, who have had a full experience of it are convinced of its absolute value.

3 The unit should be arranged in rooms of five to eight beds, with at least one two-bedded room where, for special clinical reasons or for a companionship which is psychologically necessary, two children may be lodged. In addition, single rooms will be required for 5-10% of the total number of patients.

4 In each unit, or conveniently near to each unit there should be a suite of special rooms in which, when necessary, a mother may live with, nurse and care for her own child. She will do this under supervision of the trained staff. Five or more rooms of this sort will be required in a unit of fifty beds.

5 In each unit there should be a small self contained traumatic department into which the injured child may be immediately received and treated.

6 In each unit there should be a treatment room in which all dressings, lumbar punctures, and other painful manipulations can be carried out, and where anaesthesia will be frequently used particularly for the painful removal of dressings.

7 Each unit should contain its own laboratories in which the clinical staff can work and carry out such immediate laboratory examinations as are within their province. One skill enhances another skill. The clinician who has undergone a laboratory discipline and who himself continues so far as he can, to use precise laboratory methods in his wards is likely to be a more accurate observer and a closer student of disease than he otherwise would be.

8 Each whole-time worker in the unit, whether he be house-physician or senior member of the staff, should have in or near the unit "a room of his own" however small it may be.

Medical Staff

The care and treatment of children in hospital demands from the medical staff more time and more attention to detail than does the care of adults. Therefore the primary responsibility for the immediate clinical work in a children's unit should be placed fairly and squarely on the shoulders of one person. In my opinion this should be a resident paediatric physician who has been fully trained before taking up the post and who will hold it for two to four years. It is exacting work, and two to four years is long enough for that kind of responsibility. The resident paediatric physician will require the help of other residents, one of whom will be experienced enough to be his deputy. In a busy clinical unit of fifty beds there should be at least three residents. There should also be a senior paediatric physician and his deputy who visit regularly and who are readily available for consultation. They will be responsible for ultimate decisions, for the maintenance of standards in the nursing and treatment of the patients, and for the promotion of inquiries into all aspects of the clinical work, from the control of ward infections to the control of admissions. In a teaching hospital where there are associated consultation duties, at least one of the senior physicians should be a whole-time member of the staff. Other visiting physicians, surgeons, and specialists should be members of the staff and visit regularly or be called in consultation.

This method of staffing is designed for a combined clinical unit, the value of which I press, because it is in such a unit that surgeons and specialists can most confidently place their patients, in the knowledge that the post operative progress will be constantly supervised. In teaching hospitals and departments there are other compelling arguments for the combined clinical unit. It brings together in close consultation physicians, surgeons, and specialists over the large number of patients whose diagnoses are in doubt. It has the reciprocal action of enlisting the interest both of physicians and of surgeons in new subjects for research. It solves the problem of where to place the "no-man's-land" diseases such as general injuries and staphylococcal septicaemia with osteitis. It gives to the residents a wholesome clinical experience in differential diagnosis and the after-care of patients. No paediatric physician can practise successfully unless he be an authority on the diagnosis of appendicitis. No children's surgeon can confidently advise operation without considerable skill in the differential diagnosis of acute medical diseases or without a knowledge of the use and misuse of modern methods of resuscitation. They will best get this experience and skill in a combined clinical unit of not less than fifty beds.

This staffing of a children's clinical unit may sound extravagant. But is it so? Each town with a population of 250,000 will need a general children's hospital or department of 100 beds, an associated hospital for infectious disease of the same size, and a long-stay hospital of more than fifty beds. A town of that size will be spending not less than £500,000 a year on the public education of its children, and £40,000 or more a year on its child welfare services. Against these vast sums the amount which would be spent on paediatric physicians and surgeons is very small. But it must not be too small. We must escape the poverty-stricken attitude of a hundred years ago which still encumbers us.

Nursing

In children's wards the patients and medical staff are in the hands of their nurses to a precarious extent. Rarely in an adult ward does a patient die from a fault in nursing, whereas in children's wards it happens too often to allow us any composure of mind. The fault is not always obvious, nor is it always in the nurses. More often it is in the hospital itself or in the staff, who impose upon the nurses tasks beyond their capacity. The Paediatric Committee of this College in their recent report have shown where some of the faults lie, I need therefore say no more on that score, but leave it in the hope that the heavy hand of authority and precedent will be lifted by wise reform in nursing education. My purpose in discussing nursing is to draw attention to a more particular need, and one which is likely to increase in the future.

The most difficult and time-absorbing task in nursing is the care of the youngest children, who must be nursed, fed, and changed at frequent intervals of the night and day. If in addition there is much technical treatment the care of one infant becomes one woman's work. If there must be off-duty periods, it will be two women's work. If we introduce the three-shift system, it will be three women's work. While these infants are in hospital their mothers are at home suspended in anxiety. It would seem logical, therefore, that a solution of the problem should be found in admitting the mothers to the hospital to nurse their own children. This is no theoretical proposal. I have worked under this arrangement for many years, and I count it an indispensable part of nursing in a children's unit. Nor is it a revolutionary idea. By far the greater part of sick children's nursing is already done by mothers in their homes. Not all illnesses will be suited to this nursing, but the majority of all children under the age of 3 derive benefit from it. The mother lives in the same room with her child. She needs little or no off-duty time because the sleep requirements of a mother fall near to zero when her own child is acutely ill. She feeds the child, she tends the child, she keeps it in its most comfortable posture, whether on its pillow or on her knee. The sister and nurse are at hand to help and to administer technical treatment to the child.

The advantages of the system are fourfold. It is an advantage to the child. It is an advantage to the mother, for to have undergone this experience and to have felt that she has been responsible for her own child's recovery establishes a relationship with her child and confidence in herself which bodes well for the future. It is an advantage to the nurses who learn much by contact with the best of these women not only about the handling of a child but about life itself. It is an advantage to the other children in the ward for whose care more nursing time is liberated. In teaching hospitals it is of further advantage to the students who gain a practical experience of the form of nursing they will depend on in their practices and learn to recognize the anxieties and courage which bind the mothers

to their children during illness—a lesson which fosters the courtesy on which the practice of medicine depends. I advocate this method of nursing, not on sentimental grounds but on the practical grounds of efficiency and necessity. Apart from all other reasons the shortage of nurses will impose this method on us in the future.

Care of Children in Special Hospital

About a third of Newcastle's children admitted to hospitals enter the fever hospitals. In some towns the proportion is higher. A considerable number of these patients are infants and young children suffering from illnesses other than the acute specific fevers. Apart from diphtheria which may justify this specialization of a hospital, there appears to be little reason for the sharp division between the fever hospitals and the acute medical sections of the children's department. A family is stricken with streptococcal infection. One boy develops a quinsy and stays at home, his brother has a sore throat with a rash and is sent to a fever hospital, and his infant sister gets streptococcal septicaemia and meningitis and is admitted to a children's hospital. An infant with infective gastro-enteritis which yields a dysentery organism goes to a fever hospital, another infant with gastro-enteritis which is equally infective but yields no dysentery bacillus remains in the children's hospital. Both types of hospital make their contribution to the care of children and the study of their diseases, but as time goes on each approximates to the other in its techniques and in the scope of its work. The corollary of this is that the staffing and nursing of both types of hospital should approximate also. The staffs of the fever hospitals should be trained as paediatricians and be specially instructed in the hospital care of children, and by contact with paediatric hospitals they should keep in touch with advances in the subject. On the other hand the staffs of children's hospitals should know their fevers, and be *au fait* with all advances in their prevention and control.

So far I have been discussing institutions which are thoroughly familiar to us, institutions in which we live or work each day. If at times we tend to neglect the comfort and emotional welfare of the children in these institutions by leaving that responsibility to others, we are quickly brought back to reality by contact with questioning parents. I now pass on to another type of institution where the care of children is not so readily safeguarded. This is the long-stay hospital—the orthopaedic hospital, the children's sanatorium, and the like—where patients may remain for months or years, where the medical staff who dictate the length of stay may know little about the parents of the children, where the parents may never have the opportunity of discussing the effect of confinement on the future of the child with someone who has carefully considered that aspect of its welfare.

If Samuel Butler had extended his Erewhon to include this problem no doubt he would have said that a decision to restrain and confine a person for six months for a civil offence would be reached only after hours or days of careful consideration of the evidence by a judge and a number of other trained people, but that a child, on whom the effects of confinement are much greater than on an adult, could be committed to hospital for far longer periods with far less consideration of the evidence or the need. I have experimented in the domestic care and treatment of children with active abdominal tuberculosis of children immobilized by orthopaedic appliances, of children with chronic disease which requires frequent observation and examination, and from these experiments I am convinced that too often and too lightly is the decision made to confine children.

long-stay hospitals. Sometimes the primary diagnosis is at fault. A child with coeliac disease may lie for months in bed under the impression that he has tuberculosis. Sometimes the assessment is at fault. A child with rheumatic heart disease may lie for months when he would be better gently idling about in his own home and garden. The crux of the matter is the careful ascertainment before the child is admitted, of the clinical problem of parental attitude, of their domestic circumstances, and of the conditions of the hospital to which it is proposed to send the child. This ascertainment can be made only by people with considerable clinical experience and knowledge of society.

Some of the long-stay hospitals have attempted to set their house in order, with partial success. But a long-stay hospital can never be completely successful in providing the things of which the child is deprived, whatever the educational arrangements may be, or however many their books, toys, and cinemas. These may mitigate the deprivation, but do not give the sense of personal attachment, the relationship, the companionship, which are necessary exercises for the mind of the growing child. I have had to listen to a great deal of evidence from men and women who spent much of their childhood and adolescence in these institutions. The sensitive and intelligent witnesses recalled with nightmare memories the long hours of winter evenings which pressed upon them in their adolescence, the aimlessness of their existence, the uncertainty of their future. They had their lessons each day, and raffia work and entertainments, but there was no intimacy with anyone who could explain to them the purport of their illness or encourage them with plans for the future. The fault lies in the form and arrangement of most of these long-stay hospitals. They have been conceived too much as medical institutions and arranged too much as hospital wards. It would be better if the children lived in small groups under a house-mother, and from there went to their lessons in a school, to their treatment in a sick-bay, and to their entertainment in a central hall. There would be no disadvantage in the house-mother having had a nursing training, but that in itself is not the qualification for the work she will do. Her duty is to live with her group of children and attempt to provide the things of which they have been deprived.

I must consider one other type of hospital, which will bring me full circle to Charles West again. He left obstetrics to concern himself with children's hospitals. So it is not inappropriate that a children's physician should turn for a moment to maternity hospitals, for in these places one-third of the children of the country begin their lives.

So far I have been suggesting that many of the faults in our hospitals are due to poverty-stricken ideas, which took their origin a hundred years ago and to a formal method of construction and staffing which precedent has laid upon them. This is as true of maternity hospitals as of others. Some are now escaping from poverty and are much gayer than they were, with coloured oilcloths, stainless steel, and plate glass, but there has been little reform of essentials.

What are these essentials? I take it that the function of a maternity hospital is to deliver a woman safely of her child, and afterwards to care for them in such a manner as to ensure their health, to establish their intimate and interdependent relationship, and to leave the woman free from the fears of having another child. Our maternity hospitals are ensuring the safe delivery of a woman to a greater and greater degree, but are they fulfilling the other two functions?

I know maternity hospitals which are the hygienists' dream of perfection. The women lie for their ten days in immaculate beds placed equidistantly along sterile walls. Their ward is a picture of calm repose and passive immobility. You ask what has happened to create this atmosphere of silence and subdued conversation and fail to get an answer, but the truth is that the mothers are mystified by an arrangement under which their babies have been taken away from them at the time when, at the end of nine months' waiting, they had expected to possess them. The babies are in cots set in rows in a room along the corridor beyond their earshot, out of sight but not out of mind. At regular intervals of the day they are placed on a trolley, wheeled along the corridor, and with the ringing of a bell which announces that milking-time is at hand, they are delivered by a masked woman to another masked woman at the door of the ward in which the mothers wait. Milking-time over the babies are re-embartered for their nursery where they are solaced with sugar and water.

- This, surely, is physiologically wrong. I and many of my colleagues have the advantage of working in maternity hospitals where, throughout the puerperium night and day mothers and babies are kept within reach of each other where the mother may pick up her baby when she desires where everything that is done for the child is done within sight of the mother at her bedside, and experience shows that with simple precautions not only is the danger of neonatal infection less than it otherwise would be, but breast feeding and the relationship between mother and child are firmly and safely established in a physiologically natural manner.

Co-operation between obstetricians and paediatricians is now becoming close, but concerning this I have one piece of advice to offer. It is next to useless to enlist the services of a paediatrician in a maternity hospital only to visit occasionally and give advice on sickness. In a maternity hospital of any size there should be an experienced paediatric physician who lives there, or visits each day regularly and punctually. It is his or her duty to prevent and treat sickness in the children, and to apply a knowledge of human biology on which the relationship between mother and child is founded. The paediatric physician will have his own technique of ward rounds, of control of infections, of treatment of disease, all of which demand a special knowledge. In smaller hospitals which cannot find such an experienced person for their staff, at least one of the obstetric officers should have a training in this branch of clinical work and human biology which fits them to supervise that aspect of child-care.

Conclusion

Although I may have failed to make it clear the tenor of my discourse has been that the care of patients in hospitals is a subject which demands scientific study, and experience based on such study, and that the need for this is greatest of all in children's hospitals. A children's hospital is an instrument of medical treatment. It is a highly specialized instrument, and its arrangement must be constantly altered and adapted to meet changing needs. It is also a dangerous instrument in the hands of those who do not know how to use it.

These difficulties and dangers should be exposed in constant inquiry and discussion, and corrected by research. For this purpose some members of the profession, themselves experienced in the work of children's hospitals, must make themselves expert in the physical examination of institutions. No amount of administrative or clinical experience alone will fit them for that work.

CHANGES IN HAEMOGLOBIN CONCENTRATION IN THE ACUTE STAGE OF LOBAR PNEUMONIA

BY

MARGARET S FERGUSON, M B
Knightswood Fever Hospital Glasgow

The frequent occurrence of delayed resolution in lobar pneumonia treated with sulphonamides has emphasized the need for the investigation of factors which might lead to further elucidation of the process of resolution. Ross (1945) demonstrated that those patients who subsequently developed delayed resolution had, on admission to hospital, a lower concentration of plasma protein than those whose consolidation resolved within the normal time. Although it seemed possible that such low plasma proteins might be due to a dietetic deficiency in protein, she also suggested that the onset of pneumonia might itself cause a fall in the plasma protein content. It seemed reasonable to argue that if a loss of plasma protein were initiated by the disease process, the presence of "oligaemic shock," with accompanying haemoconcentration, might be a factor in the severe case of pneumonia and might retard the process of resolution. It was therefore decided to repeat Ross's experiment, with the addition of a careful study of the course of the haemoglobin concentration.

Methods

The investigation was carried out concurrently with, and upon the same subjects as, an experiment comparing the respective therapeutic effect of sulphonamides and penicillin on the course of lobar pneumonia (Anderson and Ferguson, 1945). The patients were men of 35 years or more. They received either sulphonamide or penicillin therapy. Already it has been recorded that the results of treatment were similar. Further as a careful comparison of the haemoglobin changes in the two groups showed no difference between them they have been regarded for the purposes of the present investigation as a single series.

Heparinized venous blood, withdrawn from a superficial vein without stasis was used for all haemoglobin and plasma protein estimations. Plasma protein concentrations were estimated only on the blood sample obtained upon the patient's admission to hospital. The estimations were made by the refractometric method.

A photo-electric absorptiometer of the Spekker type was used to estimate haemoglobin concentration. Haemoglobin was converted to oxyhaemoglobin by blowing an accurately measured 0.1 ml. of heparinized blood into 10 ml. of a 0.4% solution of ammonia in distilled water. The readings obtained on the Spekker were converted to absolute values by means of a graph. This graph had been obtained previously by plotting serial dilutions of a blood of known oxygen capacity against their corresponding logarithmic values.

Each patient's haemoglobin concentration was estimated on admission and if possible, for the four succeeding days. Thereafter unless clinical findings indicated that more frequent investigation might be of interest haemoglobin estimations were repeated only at weekly intervals. The majority of estimations were duplicated and a difference greater than 0.2 g. was considered to be inaccurate.

Results of Investigation

(a) *Admission Plasma Protein Concentration*—The admission plasma protein concentrations were estimated on 84 patients whose recovery was uncomplicated either by

empyema or by sterile effusion. These cases were divided into two groups.

Group A contained those patients in whom, by the 28th day of illness, there remained no clinical or radiological evidence of a pneumonic consolidation. Such patients were considered to have shown "normal resolution."

Group B contained all those patients in whom the pneumonic consolidation persisted beyond 28 days. Such patients were considered to have delayed resolution.

The percentage frequency distribution of the plasma protein concentration in these two groups is shown in Fig. 1 and Table I. It is apparent that the majority of Group B

FIG. 1—Admission total plasma protein level

TABLE I—Admission Total Plasma Protein Level (Actual Figures)

	Protein Level in G.					Total No. of Cases
	4.1-5	5.1-6	6.1-7	7.1-8	8.1-9	
Cases resolving in 28 days	2	5	13	18	4	40
	5%	7.5%	32.5%	45%	10%	100
Cases resolving after 28 days	4.5	8	20	12	2	44
	4.5%	18.2%	45.5%	27.3%	4.5%	100%

cases on admission to hospital have a lower concentration of plasma proteins than have Group A cases, for in 55% of Group A cases a plasma protein concentration of between 7.1 and 9.0 g. % was obtained whereas only 31.8% of Group B cases attained this level. These figures confirm Ross's observation except that in the present series the differences are less marked. It may be noted that Ross's cases included all male patients from 20 years of age upwards, whereas the present series contains only patients over 35 years. Since this selection concentrates attention on the age group in which the disease is most severe it would be natural for the difference to be less obvious.

(b) *Admission Haemoglobin Concentration*—The distribution of admission haemoglobin concentration in all

TABLE II—Correlation Between Admission Haemoglobin Concentration, Duration of Illness and Subsequent Time of Resolution

	Hb Concentration (G. %)						% of Cases showing		Total No. of Cases
	19-17	17-15	15-13	13-11	11-9	Aver	Normal Resol	Delayed Resol	
All cases on admission	1	15	53	38	4	13.48			111
Cases admitted on 1st to 3rd day of illness	1	7	35	18	1	13.65	61.4	38.6	62
Cases admitted on 4th day of illness and over	—	8	18	20	3	13.26	33.3	66.7	49
Cases with Grade I consolidation	—	6	10	7	—	13.91	86	14	23
Cases with Grade II consolidation	1	5	22	17	—	13.56	41	59	45
Cases with Grade III consolidation	—	—	18	14	4	13.03	15	85	39

patients was grouped according to the duration of illness and density of consolidation. The frequency of delayed resolution in each group was also recorded (Table II). Study of this table suggests that cases admitted early in their illness tend to have an average admission haemoglobin concentration slightly higher than those admitted late and that delayed resolution is rather more common in the latter group. In an attempt to obtain some standard which might reflect the haemoglobin level before admission, nine healthy male relatives of the same age group were selected, since, living under the same conditions as the patients, they might be expected to show a similar blood picture.

The average haemoglobin concentration of these controls was 14.98 g %, a level within normal limits, and one which is in accord with that reported by Marshall (1946)—14.6 g per cent for male blood donors of this age group in Glasgow. A comparison of this figure with the average admission haemoglobin in pneumonic patients reveals that the latter is 1.5 g lower than the control figure. These figures suggested that the haemoglobin concentration was lowered by the onset of pneumonia and that as the duration of the illness increased the level might be further reduced.

It seemed possible that the effect of a longer duration of the disease might be to increase the extent of consolidation. If such were the case, then a correlation between the haemoglobin level present on admission to hospital and the density of consolidation as assessed from a radiograph might be expected. To test this, three arbitrary grades of radiographic density were chosen. These were defined as follows:

Grade I Consolidation—Those cases in which the lung markings could be seen clearly through the consolidation were allocated to this section.

Grade II Consolidation—Into this group were placed cases in which the lung markings could still be discerned through the consolidation but much less clearly than in Grade I.

Grade III Consolidation—Into this group were placed those in which the consolidation was so dense that no lung markings were apparent.

When a comparison is made of the admission haemoglobin values in these three groups (Table II) we find a slight trend downwards in the haemoglobin concentration as the density of the consolidation increases. As one might expect, there is a direct correlation between the density of the original consolidation and the speed of resolution. This is shown very clearly in that 85% of those patients with the densest consolidation (Grade III) developed delayed resolution, where-

as among those patients with the least dense consolidation (Grade I) only 14% showed this abnormality. Of more importance, however, the findings give no support to Ross's contention that "shock" might account for the low plasma protein levels in pneumonia, since the consequent haemococoncentration which should be present was not found.

Mean Daily Haemoglobin Levels during Course of Pneumonia

Since it appeared that haemoglobin concentration might be affected by the duration of illness prior to admission to hospital the

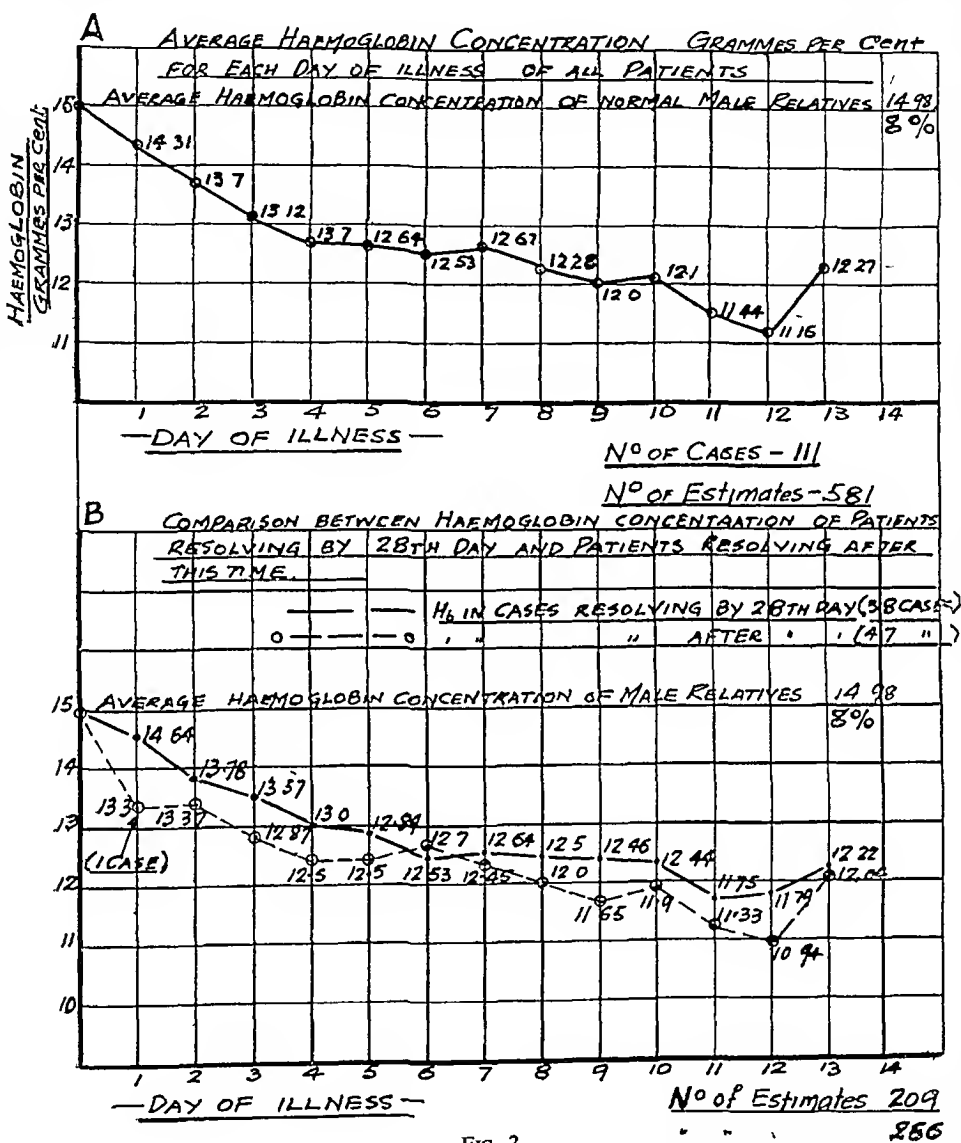

FIG 2

mean haemoglobin levels for each day of illness were calculated. The results of this analysis are depicted in Fig 2, A. It is evident that in pneumonia, during the first 12 days of illness there is a progressive fall in haemoglobin concentration which follows a steady curvilinear course. Further, a tentative suggestion may be made that, as the original haemoglobin concentration of the pneumonic patient was probably similar to that of his male relatives, a fall in haemoglobin value had already occurred before his admission to hospital.

When a comparison of the average daily haemoglobin values was made between patients whose consolidation resolved normally and those in whom resolution was delayed, the graphs shown in Fig 2, B were obtained. It can be seen that the curve for those patients who de-

delayed resolution shows a tendency to follow a rather lower level than that found in patients whose consolidation resolved within a normal period. It was now becoming manifest that haemoconcentration was not normally found in cases of pneumonia. Indeed, the haemoglobin value appeared to fall progressively below normal limits during the fastigium of the disease, this fall was most marked in cases which subsequently developed delayed resolution.

Discussion

The initiation of the pneumonic process must occasion a loss of plasma into the affected lung. It seems reasonable to assume that this depletion will be proportionate to the volume of lung affected. Loss of protein from the plasma would naturally cause a mechanical haemodilution, although in a normal healthy subject one would expect such a change to be transitory and a rapid return of plasma protein and haemoglobin to normal levels to occur within two or three days. Yet in pneumonia the haemoglobin concentration continued to fall.

Such a rapid fall in haemoglobin concentration does not seem to be in keeping with the onset of a simple hypochromic anaemia produced by a sudden cessation of iron absorption. A continuous loss of blood by haemolysis might easily produce such a result, but examination of the blood of six patients during the first five days showed no evidence of reticulocytosis. It seemed most likely, therefore, that the fall in haemoglobin concentration was caused by haemodilution, and, indeed, Rutstein and his co-workers (1945) have shown that in the acute stage of lobar pneumonia an increase does occur in both the plasma volume and the volume of the extracellular fluid.

Seaman and Ponder (1943) obtained rather similar findings in post-operative cases and showed that after operation the fall in haemoglobin concentration was greater than could be expected from the volume of blood lost. Findings so similar in two entirely different conditions might suggest that in each, the phenomenon may be a response to injury. It may be that the injury to tissue, no matter what the assaulting mechanism be, produces a depression of the haemopoietic system.

Madden and Whipple (1940) express the view that the liver produces all albumin and much of the globulin required by the body, and observe that there is some evidence to show that, in dogs, infection can limit protein formation. If the haemopoietic system were thus depressed the liver might not only be unable to restore the plasma protein lost initially into the lung but also might be inadequate in replacing the normal physiological daily loss. A similar continuous decrease in the number of circulating erythrocytes might also result. Such a loss of plasma protein might be expected to produce a fall in osmotic pressure and a resulting decrease in plasma volume with marked peripheral failure. Yet in pneumonia there is an increase in plasma volume.

It is interesting that in nephrosis, despite a very low plasma protein concentration a normal or almost normal plasma volume is found. Warren, Merrill, and Stead (1943) have suggested that the presence of an increased extracellular fluid volume may be the mechanism whereby the plasma volume is maintained in this disease. In experiments on dogs these workers have demonstrated that when the extracellular fluid was increased by continuous infusion until oedema occurred a normal plasma volume could be maintained despite a continuous loss of plasma protein.

It seems possible that in pneumonia retention of orally administered fluid produces a similar phenomenon and

that the extravascular fluid and plasma volume remain increased until such time as the factor which inhibits the production of new plasma protein and fresh erythrocytes is overcome.

These findings might be linked with the lowered blood chloride levels and chloride retention found in pneumonic patients. If an excessive quantity of vascular and extravascular fluid were present then it would not be surprising that a concurrent retention of chlorides should occur and that, despite this, the chloride concentration in the blood should be low.

It would thus appear that low plasma protein and low haemoglobin levels found in pneumonia are not in themselves causative factors in delaying the speed of resolution but that these findings indicate an extensive and dense consolidation which is itself a prime factor in the speed with which resolution is concluded. There would seem to be need for further study of the biological changes to which the onset of an infective process gives rise.

Summary

The haemoglobin concentration of patients suffering from pneumonia was studied by repeated examination over a period covering the acute stage of the disease. There was no evidence of haemoconcentration. The haemoglobin concentration fell progressively during the first 12 days in hospital. It is suggested that this reflects a haemodilution found most markedly in the severe case.

The presence of low plasma protein concentration and low haemoglobin in cases of pneumonia does not cause delayed resolution but merely parallels the density of the consolidation, which is itself important in deciding the time of resolution.

I wish to thank Dr Thomas Anderson for much helpful advice and criticism.

ORDER OF ST JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in and appointments to the Venerable Order of the Hospital of St John of Jerusalem

As Knights Major Gen Sir R B Ainsworth, C B, O B E, D S O, K H P, Surg Vice-Admiral H St C Colson, C B E, Air Marshal Sir Andrew Grant K B E, C B, K H S, Dr E Llewellyn *As Commanders (Brothers)* Major-Gen P H Mitchiner C B, C B E, T D Col A R S Vickers, Drs R B MacGregor CMG, F W M Palmer *As Associate Commander (Brother)* Major S A Paymaster, I M S *As Commander (Sister)* Dr Frances C B MacKay *As Officers (Brothers)* Brigs C Scales M C, D G Cheyne C B E, M C Col R J Poston, T D, late R A M C, Cols C G L van Dyk, G G L Stening, Lieut-Col J C John O B E, I M S, Lieut-Col C M Forbes (since deceased), Major J H Plumridge, R A M C, Drs R Nelson, J C R Buchanan, R D Jones R J Walker, J J Mangion, M C Lavin, H B Pare, Chau Wai Cheung Tseung Fat In *As Associate Officers (Brothers)* Drs S J Hoffman, P K Chatterjee *As Serving Brothers* Drs J W Sandoe, J Orr, J R B Dearden, E E Parrett, J A G Wilson, R B Radcliffe, I Davies, I H Davies, I H Lloyd, T W White, N C Joel, A J J O Sullivan, H H Goodman W L Walker, R B Eadie, J Craw, J Morris, H A Robertson, A D D Broughton K M Rodger, A C Ternes, L S Woods, E R Beech B W Buttsworth L D Hodby, A N Jacobs, R B Knight, H H R Nash *As Associate Serving Brothers* Drs K Budeim, E Galgut, G C Roi, R K Bhandari *As Serving Sisters* Drs Winifred M Cole, Isobel C Allardice, Roberta H M Jull

FOOD UTENSIL BACTERIOLOGY

BY

R. IRENE HUTCHINSON, MB, DPH, DTM

Public Health Laboratory Service

Modern conditions compel many people to have meals in communal feeding-places, and much work has been done on outbreaks of enteritis following the consumption of meals contaminated by infected "food-handlers." Not so much attention has been given to the possibility of transfer of similar and other infections by food utensils.

To ascertain the general hygienic condition of the "messing equipment" in daily use by the public a survey was made in 25 kitchens. These included A A and R A C approved hotels, restaurants of multiple stores, works and school canteens, day nursery kitchens, cashops, snack-bars, and a civic restaurant. Visits were made between 12.30 and 1.30 p.m., so that conditions were observed at the peak hour when they were at their worst. The visits were not pre-announced, so that no special cleaning could be done. The kitchens were situated in a residential area of about 60,000 inhabitants—a London dormitory town where the food inspection was maintained at a very high level.

Samples of washing-up water in actual use were taken and swabs of spoons, cups, forks, glasses, and plates which had been used, washed, and were stacked ready for re-circulation. The swabs were moistened in nutrient broth, and for cups an area of 2 sq in (12.9 sq cm) to the left of the handle was rubbed over on the assumption that this area was most likely to contain organisms. For glasses the rims and inner and outer surfaces to a depth of 1/2 in (1.25 cm) were covered, and for forks the free ends of the prongs for a depth of 1 in (2.5 cm).

Organisms Isolated from Utensils

Spoons—Out of 164 examined, 8 grew a coagulase-positive *Staphylococcus aureus*, 2 a Group B haemolytic streptococcus, 1 a *Bact. dysenteriae* sonnei, 1 a paracolon bacillus, 2 *Bact. faecalis alkaligenes*, and 27 yielded coliform bacilli.

Cups—Out of 121 examined 9 grew a coagulase-positive *Staph. aureus*, four haemolytic streptococci (2 Group C, 1 Group B, and 1 Group G), 2 paracolon bacilli, 2 *Bact. faecalis alkaligenes*, and 30 yielded coliform bacilli.

Forks—Out of 219 examined 8 yielded a coagulase-positive *Staph. aureus*, 2 haemolytic streptococci (1 Group A, 1 Group G), 2 paracolon bacilli, 1 *Bact. faecalis alkaligenes*, 1 *Proteus* bacilli, and 43 yielded coliform bacilli.

Plates—Out of 53 examined 6 grew a coagulase-positive *Staph. aureus*, 2 haemolytic streptococci (1 Group B and 1 Group G), 2 *Bact. faecalis alkaligenes*, 1 *Proteus* bacilli, 3 *Pseudomonas pyocyanea*, and 23 yielded coliform bacilli.

Glasses—Out of 58 examined 3 grew a coagulase-positive *Staph. aureus*, 4 haemolytic streptococci (2 Group B and 2 Group G), 1 *Bact. faecalis alkaligenes*, 1 Morgan's bacilli, and 10 yielded coliform bacilli.

All these organisms except the coliform bacilli are possible pathogens and have been cited as causes of disease. The widespread occurrence of coliform bacilli would suggest a real possibility of contamination by intestinal pathogens. No attempt was made to classify these coliform bacilli, as high counts of the dish-washing waters grown at 37° C suggested that the majority were of animal origin. Faecal streptococci, *Streptococcus viridans*, and *Staph.*

albus were also grown from 588 of the utensils examined, only 27 yielded no growth of any kind. These organisms, although not pathogenic in themselves, are an indication of the degree of possibility of infection from mouth and bowel organisms.

Dish-washing Waters

Thirty-eight samples of dish-washing water were examined, 19 had counts of more than 1,000,000 organisms per ml at 37° C and 9 had counts of more than 1,000,000 organisms per ml at 22° C. Twenty of the 38 had considerably more organisms growing at 37° C than at 22° C—the approximate proportion being 120:1—suggesting the presence of a much higher number of organisms of animal than of soil or dust origin. As the average crude sewage in this country contains approximately 1,000,000 to 5,000,000 organisms per ml at 37° C (Topley and Wilson, 1946), it is seen that the majority of the dishes are being washed in water that bacteriologically is equivalent to sewage.

Twenty-three of the 38 waters had more than 1,800 coliform bacilli present per 100 ml. The Ministry of Health standard for a potable water varies according to the origin, but is ideally no coliform bacilli in 100 ml, and waters are "satisfactory" only if they have not more than 2 coliform organisms per 100 ml. Hence, these waters used for washing utensils, most of which are to be placed in the mouth would appear to be entirely unfit for such a purpose.

Owing to the difficulty of obtaining soaps and soda 11 of the 38 waters contained no detergent. In others soda had been generally added, but in varying proportions—a handful or so being thrown in at random. That the addition of soda is of value is shown by the following.

With pH range 7–10 67% waters had bacterial counts greater than 1,000,000 organisms per ml.

Over pH 10 only 35% waters had bacterial counts greater than 1,000,000 organisms per ml.

With pH range 7–10 67% waters had coliform bacilli greater than 1,800 per 100 ml.

Over pH 10 only 47% waters had coliform bacilli greater than 1,800 per 100 ml.

The temperatures of the waters were found to be exceptionally low—the average was 40° C—the maximum being 50° C and the minimum 30° C. These temperatures would of course be too low to have any destructive or inhibitory effect on any organisms.

Among the organisms isolated from these waters were *Streptococcus viridans*, faecal streptococci, *Staph. albus* and *aureus* (coagulase-positive), coliform bacilli, paracolon bacilli (8 times), *Bact. faecalis alkaligenes* (12 times), *Proteus* bacilli (once), *Pseudomonas pyocyanea* (8 times), and aerobic sporing bacilli (14 times).

Drying Cloths

In most cases, owing to the shortage of towels and the impossibility of a quick laundry service, cloths were used till wet, and then dried and re-used. Many were washed at night and sent to the laundry weekly. Seventeen of the 36 examined yielded only faecal streptococci, *Staph. albus*, *Str. viridans*, and aerobic sporing bacilli. From the others one or more of the following were grown: coliform bacilli, paracolon bacilli, coagulase-positive *Staph. aureus* and *Bact. faecalis alkaligenes*. On the whole the cloths did not seem too unsatisfactory.

The cleanest utensils came from a multiple store where a washing machine, with soda, was used and where there was no hand-drying of cups, plates, and glasses. They were placed in a drying oven with a temperature of

approximately 82° C, their length of stay varying from a few minutes to half an hour according to the demand for them. This temperature was high enough to kill many of the more delicate organisms, and indeed 10 out of the 20 swabs were sterile. This compares very favourably with the other 24 kitchens, where only 17 sterile results were obtained from among 595 swabs.

Though this investigation was not concerned with the bacteriological examination of the 'food-handlers' in the kitchens, advantage was taken of the visit to inspect the sanitary arrangements and washing facilities provided for them. In most cases these were unsatisfactory. In 14 places no washing facilities were available either within or immediately adjacent to the sanitary convenience, and hands had to be washed, if indeed they were washed at all, in the same kitchen sink as the crockery and cutlery. This provides a sure path of infection by intestinal pathogens.

Conclusion

It would seem from this brief survey that in communal feeding-centres the cleaning of eating utensils is very unsatisfactory, and that pathogenic organisms are likely to be spread among the users of different articles. The lack of modern equipment such as washing machines, the difficulty of obtaining soap and washing powders, and the scarcity of drying towels renders very difficult the important and necessary task of feeding people in a hygienic manner. The finding of dysentery bacilli on the cutlery in one out of only 25 kitchens is rather disquieting, and may suggest the origin of the sporadic case of "diarrhoea", and the finding of pathogenic streptococci 14 times and of pathogenic staphylococci 36 times may help to explain the high incidence of septic mouth lesions so common in the last few years. The prevalent method of washing and drying infected crockery and cutlery appears to do little in the way of destroying their pathogens.

Very great interest was shown by the proprietors of the premises visited and every help was given to facilitate the investigation. Results were keenly awaited, and they were eager to know what measures could be adopted to remedy defects. It would seem that public health propaganda for improvement in kitchen hygiene, together with suggestions as to the methods to be followed, would be welcomed, especially if accompanied by bacteriological evidence showing its necessity.

My grateful thanks are due to the Medical Officer of Health for approval and permission to work in his district, to the Chief Sanitary Inspector, without whose co-operation and active help this work could not have been done, and to my technicians Mr P G R Browne, Mrs R Udall and Mr H Gillies, for much willing help in the preparation of media.

For the 1946-7 academic year 248 graduates and others of like status from overseas have been awarded British Council scholarships which enable them to take a wide range of postgraduate courses of study in this country. The scholarships are normally for one year but extensions are granted in suitable cases. In addition the British Council has helped to place many students who have come under the auspices of overseas authorities or privately. The Council during the year established a students welfare department to deal with the reception and non academic welfare of scholarship holders and to help them to gain a general knowledge of British life and institutions. To this end vacation courses, which enable those residing in London to visit the provinces and vice versa as well as term time talks, discussions, shows of documentary films, and other events are arranged. These facilities are available also to students sponsored by the Colonial Office, the Indian and Sudan Governments and to other overseas students. The year's British Council scholarship holders have come from some fifty Empire and foreign countries and include 26 taking medical subjects.

THE SURGICAL TREATMENT OF CHRONIC FRONTAL SINUSITIS

BY

V E NEGUS, MS

In my experience few complaints produce so much disability or suffering as chronic infection of the frontal sinus. In a great number of instances this suffering appears to be unnecessary, and I am therefore impelled to record my suggestions as to how unsatisfactory results may be avoided.

In the first place it is necessary not to exaggerate the incidence of frontal sinusitis, and to avoid operating under a mistaken diagnosis. The prominent symptom of frontal headache is attributable in many instances to neuralgia of various types or to migraine, but with no cause in the frontal sinus. The incidence of sinus headaches may, according to Proetz (1943), be no more than 5%, but when there is such a cause the case is difficult to cure. It is not my intention to enter into a discussion on the differential diagnosis of frontal headaches, but rather to suggest means of relief when the cause has been established.

Two Important Points

First, it is necessary to eliminate all contributory factors in the nasal fossae; this advice may seem obvious, but in a large number of unsuccessful cases referred to me this elementary detail has been overlooked. The treatment referred to is the care of infection in the maxillary and ethmoidal cells, the straightening of a high deviation of the septum, and the removal of an enlarged and obstructing middle turbinal body. Several patients I have seen have been submitted to more than one external operation while the septum has been so twisted as to make the nasal fossa on the affected side quite inadequate for ventilation and drainage.

The second recommendation concerns direct treatment of the infected frontal sinus after all preliminary measures have been taken to provide a satisfactory outlet to the fronto-nasal duct, as outlined above. I do not believe that internal operations on the frontal sinus are satisfactory; evidence is afforded by a number of patients so treated who have subsequently come under my care and have required an external operation for their cure.

The most skilled operator in this region that I have seen was Dr Max Halle, of Berlin, but even though I admired his dexterity in creating a free passage into the frontal sinus, the difficulty of clearing all infected ethmoidal cells by the intranasal route, together with the tendency of the exposed bony canal to reclose, has prejudiced me against this and other similar methods.

One comes therefore, to the final determination that in cases with chronic infection of the frontal sinus associated with the usual symptoms of headache, difficulty in concentration, depression, and so on, the correct treatment is an operation by the external route. It remains then to decide what method is desirable.

Method

Attempts at obliteration of the frontal sinus are, in my experience usually unnecessary, generally disfiguring and often ineffective. I have had to operate on several patients who had elsewhere been submitted to attempted obliteration of the sinus. The anatomical structure is such that unless a new and permanently enlarged fronto-nasal duct is created an inefficiently drained recess will be left in the lower part of the sinus, with continual suppuration and the continuance of the symptoms which the operation is intended to relieve.

If an adequate fronto-nasal duct is provided the frontal sinus is in the great majority of cases able to return to a normal state, provided the lining mucosa has not been disturbed. In four cases I have had to remove the anterior wall of a shallow sinus to obliterate outlying recesses. In these the mucosa failed to recover after reconstruction of the fronto-nasal duct, but such cases are rare, and even with them it is essential to provide a free communication between the remains of the sinus and the nasal fossa, so that the first operation is not wasted. In this connexion it is interesting to note that in five cases in which previously unsuccessful attempts at obliteration had been made I have secured a good result by establishing an adequate fronto-nasal duct while at the same time reconstructing the frontal sinus by means of a saccular skin-graft. Not only has suppuration been eliminated thereby, with cure of the previous symptoms, but a good cosmetic result has been attained by restoring the contour of the forehead.

Reviewing the records of over a hundred patients on whom I have operated, the conclusion has been arrived at that a cure can usually be obtained by re-establishing ventilation and drainage of the sinus, the lining being undisturbed and allowed to return to normal. I do not believe that curettage of the cavity is necessary or desirable. I have, in various instances, found pockets of infection in such cases and have had to reoperate, sometimes replacing the denuded lining of the sinus by the insertion of skin, as referred to above. A considerable number of the patients I have dealt with had had one or more previous operations on the frontal sinus, and one young man had undergone, according to his own account, a total of seventeen.

Leaving, therefore, the anterior wall and the lining of the sinus, one has to decide on the route to adopt. I am of the opinion that a short incision, curving round the inner margin of the orbit, well away from the inner canthus, gives the best approach. A clear view is provided for clearance of any remaining infected or obstructing ethmoidal cells, there is no danger of damage to the trochlea or lacrimal sac if the orbital periosteum is carefully detached. The base of the skull is visible and safety is attained in enlarging the opening between the sinus and the fossa. It is unnecessary to remove more than a small portion of the floor of the sinus, but it is essential to take away a considerable part of the nasal process of the maxilla, as advocated by Howarth. Approach by an incision lower down seems to me to be inconvenient and to make permanent restoration of the fronto-nasal duct difficult or impossible. The operation described above allows of the gentle removal of exuberant hyperplastic mucosa when necessary, but curettage is carefully avoided. Examination of the posterior wall of the sinus for possible caries is, in my opinion, unnecessary, for the reason that even if present it is better left alone, in the certainty of ultimate recovery. This applies, naturally, to the usual chronic case and not to those isolated instances where an extradural or a frontal-lobe abscess is suspected. In not one of over a hundred cases have I had reason to regret leaving the posterior wall and its covering mucosa intact.

Finally, one comes to the means of maintaining the integrity of the fronto-nasal duct, this is readily attained by insertion of a skin-graft, applied to the raw orbital periosteum and to the exposed margins of the bone at the entrance of the frontal sinus. The graft is tucked into position after the insertion of a large tube of rubber or plastic material, it is not wrapped round the tube, since no graft is required over the nasal septum or posterior wall of the frontal sinus. Details of the operation are given elsewhere (StClair Thomson and Negus, 1937). In ten days the tube is removed, and no subsequent dilatation or passage

of sounds should be necessary, as the new duct maintains its patency and provides adequate ventilation and drainage.

Conclusion

The operation requires care and meticulous attention to detail, but in the hands of my colleagues and myself it has proved most satisfactory in curing the symptoms without disfigurement. It is advisable, however, again to emphasize the signs and symptoms that require an external operation. Unilateral frontal headache, worse in the morning, either repeated daily over a prolonged period or recurring in acute or subacute attacks, clinical and radiological evidence of infection in the frontal sinus, evidence that maxillary sinusitis has been adequately treated and that freedom to the nasal orifice of the frontal sinus in the nasal fossa has been attained—these are the factors that indicate blockage of the fronto-nasal duct, either permanent or recurrent, and these are the reasons for which the external operation should be performed.

A SIMPLE METHOD OF ESTIMATING PENICILLIN AND OTHER BACTERIOSTATICS

BY

J. FIELDING, MRCS, LRCP, DPH

Assistant Pathologist LCC Group Laboratory Mile End Hospital

The methods in current use for the estimation of penicillin have been reviewed by Garrod and Heatley (1944). They include titration in broth, inhibition zones on solid media, turbidimetric methods, and the inhibition of haemolysis by a β -haemolytic streptococcus. Most of these methods require comparatively large volumes of test fluid, or are not easily applied in a routine clinical laboratory where many estimations of body fluids may be needed.

The method presented here utilizes the fermentation of glucose in a serum-water medium, with acid production and subsequent clotting of the serum as an indicator of growth. It combines the advantages of using small amounts of test fluids, easily available materials, a clear-cut end point, with few manipulations and sufficient accuracy for all clinical purposes.

Technique

The glucose-serum medium (see below) is inoculated with 10 c mm of a 24 hour broth culture of the Oxford strain of staphylococcus per ml of medium, and well mixed. Several 25 c mm volumes of the seeded medium are placed in a row on the paraffin waxed surface of a glass slide. An equal volume of the serum or other fluid to be estimated for penicillin content is mixed with the first 25 c mm volume of medium on the slide, and serial dilutions are then made along the row by transferring 25 c mm of the mixture to the next volume, and so on. The last volume is left unmixed, as a control. The 25 c mm mixtures and the control are then taken up into capillary tubes, the ends sealed in a flame, and the tubes incubated overnight. This gives 1, 2, 1, 4, 1, 8 etc., dilutions of the fluid under test and will correspond as end points to 0.04, 0.08, 0.16 etc., unit of penicillin per ml in the original fluid.

It will be found an advantage to use a Pasteur pipette graduated in four or five 25 c mm divisions. This is the only special piece of apparatus required, and may be used for all manipulations.

The capillary tubes should be about 1 mm bore, to give a fluid column 2 to 3 cm long. Too long a column reduces the rate of growth in its middle section.

Test Organism—Any organism which is penicillin sensitive which will grow readily in fluid serum media and ferment

glucose is suitable. In routine work the Oxford strain of staphylococcus serves very well and has the advantage that the reading is made direct in units per ml. Where it is required to estimate accurately penicillin concentrations of less than 0.04 unit per ml, a more sensitive strain of staphylococcus or streptococcus must be used. The 10 cmm inoculum per ml of medium, recommended above, has been found to produce the clearest results, but the same end point is given by a very wide range of inocula.

Medium—This has the following composition

Sterile horse serum, 1 part, distilled water, 3 parts glucose to give 1% solution, Andrade's indicator to give 1% solution. Tube into sterile containers and sterilize in steamer for 30 minutes.

It is in fact, the standard Hiss serum-water medium used in testing fermentation reactions, and is supplied in the LCC Pathological Service in 2- to 3-ml volumes in screw capped bijou bottles, which are both convenient and economical and widely available to many laboratories. The medium should be quite clear after sterilization. Some batches become turbid and should be rejected. This turbidity is apparently caused by heating a too acid medium, and is avoided by adjusting the serum to pH 8 before use (Mackie and McCartney, 1945). Here again the end point is the same over a wide range of serum concentrations. 1:2 and 1:4 dilutions of the medium given above produce similar results. It is difficult in any serial dilution technique to secure exactly the same medium and inoculum in each dilution under test without elaborating a method too complicated for routine use. The use of a 25% serum medium as diluent has the advantage of approximating to these conditions in estimations of blood serum levels.

End point of Titration—Where full growth of the staphylococcus has occurred the column of fluid in the capillary tube shows opaque clotted serum, coloured uniformly pink by the indicator, where no growth has occurred the fluid retains its original transparency. The end-point is sensitive enough to justify the use of concentrations intermediate to those obtained in a single serial dilution, by utilizing two or three series starting with, say, 1:2, 1:3, and 1:5 dilutions of the fluid under test. The Table shows the results of titrating saline or serum containing 1 unit of penicillin per ml against the Oxford staphylococcus.

Table Showing Results of Titrating Saline or Serum Containing 1 unit Penicillin per ml Against Oxford Staphylococcus H

Dil	Result	Dil	Result	Dil	Result	Dil	Result
1:2	—	1:3	—	1:5	—	1:7	—
1:4	—	1:6	—	1:10	—	1:14	—
1:8	—	1:12	—	1:20	—	1:28	—
1:16	—	1:24	—	1:40	—	1:56	—
1:32	—	1:48	—	1:80	—	1:112	—
1:64	—	1:96	—	1:160	—	1:224	—
1:128	—	1:192	—	1:320	—	1:448	+

— no acid no clot — = acid only — — acid and clot

In routine work a single series is generally used and here the end point is quite sharp. One capillary-tube dilution contains clear fluid and the next completely clotted pink serum. The table shows that the dilution half-way between these tubes contains a single inhibition dose—that is 0.02 unit of penicillin per ml. Sometimes a single tube shows acid production only without clot formation and this is then taken as the end-point. The table indicates the range of error in this assumption. It compares well with other serial dilution methods, the illustration shows such a titration. Occasionally one tube is found to be clear while the next is acid with the beginning of clot formation showing as a turbidity. In this case the end point is nearer by one-third to the second of these tubes than to the first.

Comment

The above method has been used for the estimation of unknown penicillin solutions, blood serum, cerebrospinal fluid and urines with consistent results. Although it is described as a micro-estimation using the dilution technique of Fleming (1944), similar results are obtained with larger quantities of materials in test-tubes. In the case of

blood-serum titrations, haemolysis does not seriously interfere with the readings. Where test fluids are somewhat contaminated—for example urines—care must be taken to read the end-point correctly. A penicillin-insensitive contaminant may give an isolated colony in the fluid column.

Titration of a blood serum. Right-hand tube showing acid and clot is a control. From right to left serum dilutions are 1:2, 1:4, 1:8 etc. The fourth tube from the left shows acid without clot indicating a blood-serum level of 1:28 units of penicillin per ml.

surrounded by a small zone of acid and perhaps clot formation. Very little convection occurs in capillary tubes, and the effect is not distributed throughout the column.

The method may be adapted for comparing the sensitivities to penicillin of organisms which satisfy the cultural requirements given above—for example, streptococci, staphylococci, Klebs-Loeffler bacilli. The fermentable carbohydrate may of course be changed to suit the organism.

While the above description has mentioned penicillin alone, this method may be used in work with other antibacterial substances—for example, tellurite, sulphonamides, etc.

Summary

A method for the estimation of penicillin in body fluids suitable for the clinical laboratory, is described in which the fermentation of a carbohydrate in a serum-water medium is used as the indicator of growth.

This work was started at the Emergency Public Health Laboratory, St Mary's Hospital, W2, and I wish to express my thanks to Sir Alexander Fleming for the interest he has taken in it, and to Dr A. B. Rosher for his helpful criticism.

Medical Memoranda

Persistent Anaemia in a Breast-fed Infant with Erythroblastosis Foetalis

The fact that anti-Rh agglutinins may be excreted in the breast milk is becoming increasingly well recognized, but the danger of continued breast-feeding to infants suffering from erythroblastosis foetalis is not commonly realized. The following case may be of interest in view of the fact that the haemolytic process was probably maintained by the baby receiving anti Rh agglutinins via the mother's milk.

CASE REPORT

Female child, born May 24, 1946. Normal pregnancy and labour. Birth weight 8 lb (3.6 kg). Slightly jaundiced on day of birth, and this increased in intensity until she was admitted to hospital four days later. Her parents are healthy. They have one other child, aged 6½ years, who was quite normal as a baby. There was a still birth 2½ years ago, the cause of this is unknown. No miscarriages. No family history of jaundice.

On admission the baby was deeply jaundiced, the liver was just palpable, and the spleen was enlarged almost to the level of the umbilicus. No other abnormal physical signs. Blood Hb, 57%, RBC, 2,100,000 per cmm, CI, 1.3. The red cells exhibited anisocytosis and macrocytosis, and there were a few intermediate and late normoblasts. Blood group O (IV). The mother was found to be Rh-negative, and her blood to contain Rh agglutinins, the father, Rh positive. The baby was Rh positive.

A transfusion of 3 oz (85 ml) Group O (IV) Rh negative blood was given on the day of admission. The following day her Hb was 105%. During the next few days the jaundice faded gradually, and her general condition improved. She became progressively more anaemic, however, as can be seen from the accompanying chart, and on June 12 the Hb was 53%. She was again given a transfusion of 3 oz (85 ml) of Group O (IV) Rh negative blood. This transfusion gave only a slight improvement in the severity of the anaemia, and on June 21 the Hb was 53%, RBC 2,440,000 per cmm, and CI 1.1. Throughout this period the baby had been breast-fed and, in view of the prolonged anaemia, the possibility of Rh antibodies being secreted in the breast milk and absorbed by the baby was considered. An examination of the mother's milk showed it to contain weak anti Rh agglutinins. Breast-feeding

was therefore discontinued on June 24 and artificial feeds substituted. An examination of the blood two days later showed that the Hb had fallen to 38%, and a further transfusion of 6 oz (170 ml) Group O (IV) Rh negative blood was given. Three days later the Hb was 77% and since this date the Hb level has been maintained between 66% and 75%, with a corresponding rise in RBC. Throughout the period of treatment the baby has received one hog's stomach plastule twice daily.

COMMENT

It is a well-recognized fact that Rh antibodies may be secreted in the colostrum, and a case in which such antibodies were found in the milk up to the fourteenth day was described by

Langley and Stratton in 1944. In this case weak anti Rh agglutinins were demonstrated in the breast milk on the thirty-first day. Throughout the time that the baby was breast-fed the haemolytic process continued. There was a further fall in the haemoglobin level for a few days after breast feeding had been discontinued, probably due to the fact that antibodies absorbed from the milk remained active for a short period after artificial feeding had been started. The child responded well to a further transfusion, and has maintained a good haemoglobin level ever since.

My thanks are due to Dr Charles Pinckney and to Col Owen Pritchard, medical superintendent of this hospital, for permission to publish this case.

Association of Erythema Multiforme with Herpes Simplex

Urbach (1933) was the first to draw attention to erythema multiforme occurring seven to ten days after an attack of herpes simplex. Forman and Whitwell (1934) were apparently unaware of Urbach's work when they reported 12 cases of erythema multiforme associated with herpes simplex. These authors tabulated the clinical similarities between the two conditions. Both are liable to recur, particularly in spring and autumn, both are provoked by infections, especially the common cold, and both may be caused by food sensitivity, by sunlight, and by menstruation. Urbach (1937) reported a further 20 cases and described some experimental work supporting his hypothesis that an allergic mechanism is involved. Anderson (1945) reported 10 cases, and claimed satisfactory results from treatment by scarifying vaccination with smallpox vaccine four or five times at intervals of two weeks—a procedure previously found effective in some 80% of cases of herpes simplex. Six of his cases of erythema multiforme were treated by this method, four of these remained free from recurrences for from two to five years after one or two courses of vaccination, while another showed a reduction in the severity and frequency of attacks. It is of interest that in one successful case there was no history of recent herpes, but the patient had suffered from it some years previously. A new case, which demonstrates clearly the association of the two conditions, is recorded here.

An aircraftman aged 20 had suffered from "cold sores" since the age of 10, the attacks occurring most frequently in the spring and autumn. In 1944 he had his first attack of erythema multiforme. His second attack occurred about six months later. Since then he has had recurrences of varying severity every two or three months. He was first seen on Aug 21, 1946. On examination herpetic scars were discovered round the mouth, and the hands and forearms presented lesions of erythema multiforme of iris type. He said that this attack was an unusually mild one. A full blood count was within normal limits. Clinical and radiological investigations revealed no dental or nasopharyngeal infection. He is certain that every attack occurs about ten days after an attack of herpes. He has in fact come to recognize the herpes as a warning signal of a probable attack of erythema multiforme. He never has erythema multiforme without the herpes, but occasionally a mild attack of herpes is followed some ten days later by a sensation of warmth and generalized skin irritation, lasting about one day, without the development of skin lesions. He is being treated by multiple vaccination.

I would like to thank Wing Cmdr H E Bellinger for the interest he has taken in this case and for the assistance he has given me.

A Cancer Board for the counties of Lancashire, Westmoreland, Derbyshire and Cheshire, but excluding Liverpool and Warrington has been set up under the Cancer Act, 1939 to arrange facilities for diagnosis and treatment of cancer in the working area of the Christie Hospital and the Holt Radium Institute. The Board will bear the cost of maintaining and treating patients.

Reviews

BUCHANAN'S ANATOMY

Buchanan's Manual of Anatomy. Edited by F Wood Jones, M Sc, FRS, FRCS, assisted by E L Patterson, M.D., S Mottershead, M.D., FRCS, T E Barlow, M.D., F R Wilde, FRCS, and Jessie Dobson, M Sc, BA. Seventh edition (Pp 1616, 847 figures, 48 plates 45s) London: Baillière, Tindall and Cox 1946

The seventh edition of *Buchanan's Anatomy* is edited by Prof F Wood Jones, with the assistance of five former colleagues in the University of Manchester. Very considerable changes have been introduced and some deletions made, but its original character of a book on topographical or regional anatomy has been retained. The first edition appeared in 1906, and at once became popular not only in the Scottish universities but elsewhere in Great Britain. In 1925 a fifth edition was brought out in London by Professors E Barclay Smith, J E Frazer, I G Parsons, and W Wright, which was characterized by the introduction of a section on general embryology, with descriptions of later development in the human subject of special organs, which were inserted in appropriate places throughout the book. These included much of Prof Frazer's original work, supplemented by illuminating references to comparative anatomy and morphology.

From the present edition—probably owing to post war restrictions and the desirability of limiting the size of the book—certain omissions had to be made, the introductory section on embryology and the use of colours to distinguish origins and insertions of muscles, arteries, veins, and nerves, and afferent from efferent nerve tracts, have been abandoned, and it was thought best to replace the original description of general embryology and some of the later stages of development of individual organs by an introductory section dealing with general growth and development. This section, undertaken by Prof Wood Jones, contains valuable personal observations and schematic illustrations by himself of developmental changes which occur in late foetal life and those periods of postnatal development which he defines as the phases of infancy, neonatal stage, early and late childhood, puberty, adolescence, and young and full adult life. Like all Wood Jones's previously published works it bears the stamp of a keen appreciation of the interrelationship of cause and effect and in the present instance he also clearly demonstrates the need of preparation during development for future requirements—e.g., adaptations in the structure of the skull and of the respiratory and circulatory systems for the important events of childbirth, independent respiration and the ability of the new born infant to obtain nourishment by sucking, along with the powers of digestion, absorption, and excretion. Two important features in this edition are the inclusion of 48 excellent and well-chosen colour plates and the biographical notes of anatomists whose names have been associated with anatomical parts. Moreover the glossary, which was a useful feature of previous editions has been retained.

There are a few minor defects in the book which might be rectified in future editions. (1) Paginal cross references are desirable in a book on regional anatomy in which certain parts or organs are necessarily described in more than one section of the book. (2) More references to applied anatomy would greatly increase the interest and general usefulness of the work. (3) Fuller descriptions are needed with good illustrations, of the microscopic anatomy of such organs as the salivary glands, pancreas and suprarenal and genital glands. (4) In the glossary derivations and definitions are in a few instances too short or misleading—e.g. thymus G Thyme. The Greek word *thymos* has more than one meaning besides (a) thyme the plant it was employed to denote (b) the soul or spirit and (c) the glandular substance in the chest of young animals (sweet bread of Galen). The book as a whole however is remarkably free from errors and the new matter which has been introduced including recent work on the articulations and C.N.S. supplemented by numerous explanatory illustrations by the editor and the beautiful series of new plates will ensure its continued popularity.

RESEARCHES ON COLOUR VISION

Researches on Normal and Defective Colour Vision. By W D Wright, D Sc (Pp 383, 233 illustrations 36s) London: Henry Kimpton 1946

A book written by a specialist is almost always a valuable addition to the literature of the subject. This is certainly the case with the work on colour vision now under review, clearly written, with good diagrams, it is a book which can be strongly recommended. So that other prospective readers may judge for themselves, a brief survey of the contents of the book may now be given. Chapters I and II. The physiology of vision, and visual perception. Chapters III and IV. The colorimeter and its modification for different purposes. Chapters V to VII. The determination of the luminosity curve for the fovea and parafovea. Chapters VIII to XII. The results of mixing red, green and blue monochromatic colours. Chapters XIII to XVII. The discrimination of the eye for differences of hue. Chapters XVIII to XXIII. The effects of adaptation, both to white light and to several coloured lights. Chapters XXIV to XXIX. The measurement of colour vision in colour-defective persons. Chapter XXX. The interpretation of colour vision phenomena in terms of the fundamental response curves.

As indicated above, the reviewer is already finding the book an extremely useful one, because there are ready to hand many papers written by the author to which one wants to refer, and which, but for this book, would mean going to a library, with a considerable consumption of time. It is to be hoped, now that the war is over, that publishers will find it possible to produce many more books like this.

A STUDY OF MALNUTRITION

Etude des troubles causes par la denutrition dans un asile d'aliénés. By Maurice Bachelot (Pp 269 No price given) Paris: Librairie Louis Arnette

At the present time, when attempts are being made to maintain that human beings can subsist without serious damage on diets far below the minima that have been accepted in the past studies of the effects of carefully measured diets on health are particularly valuable. Dr Bachelot's book gives the results of combined investigations made at an asylum, la Maison Nationale de Charenton, and at the Institut de Recherches d'Hygiène (Section Parisienne). The patients at the asylum had been well fed up to July, 1940, from that time bread was reduced to 300 g per day, meat to 20–30 g and visible fats to 5–7 g. The death rate rose after March, 1941, diarrhoea became frequent, deaths from tuberculosis mounted from 4 to 43 per year by the end of March, 1942, some 100 cases of nutritional oedema had been detected. The amounts of nutrients supplied per day by the diet were measured on five occasions between April and December, 1941: calories and fats were at their lowest (1436 and 22.57 g) in April 1941, animal protein fell to 10.9 g in December, 1941. On the other four occasions calories were over 1,700 and animal protein was over 15.9 g per day. Some factors, particularly the frequency of intestinal infections, make patients in asylums an easier prey than normal people to the effects of such scanty food, but on the other hand they were less hard worked and were better warmed than were the general population.

The author made a special study of the relation of nutritional oedema to the concentration of albumin in the serum. As a general rule when the albumin was below 3.5 g per 100 ml oedema was extensive. Oedema occurred when the concentration was higher, but it was moderate or slight and localized, when supplementary food led to decrease of oedema the albumin rose. When oedema got worse the albumin almost always fell. But in some cases oedema disappeared when the patients were put on a salt-free diet, without any rise of the serum protein. Oedema, even if only moderate, did occur without reduction of serum albumin and might persist after the serum albumin had risen to normal. Reduction of the serum albumin appears to be the chief but not the only factor that causes oedema. It has been claimed that nutritional oedema as seen on the Continent during the war, was cured by treatment with large doses of vitamin B₁, but Dr Bachelot found that doses of as much as 75 mg per day had no effect. Supplements of foodstuffs that supplied about

calories per day caused a slow improvement, the oedema disappeared in from 6 to 10 weeks

Some of the patients developed a pellagrous dermatitis, and diarrhoea was extremely common. Doses of nicotinamide cured most cases of diarrhoea but had no effect on the dermatitis. The amount of nicotinic acid in the diet (159 mg per day) was not low, the appearance of signs of pellagra on such a diet is interesting in view of the new theories of the relation of pellagra to inadequacy of protein in the diet. The authors consider less fully the other manifestations of pellagra, the course of tuberculosis, and the terminal stage and morbid anatomy of malnutrition.

PRACTICAL ANAESTHETICS

A Short Handbook of Practical Anaesthetics By Noel Parry Price, M.R.C.S., L.R.C.P. D.A. (Pp 127 illustrated 12s 6d) Bristol John Wright and Sons 1946

The author of this chatty little book is obviously an anaesthetist of experience. He writes not as an instructor but as a friend telling the reader in a confidential manner such things as the secrets of successful technique and how to avoid the innocent-looking pitfalls which all too often cost a patient his life. The friendly communion between author and reader is effected by a pleasant, easy style of writing which will make the book acceptable for armchair reading after a busy day.

Rightly, in a small volume of this sort Dr Parry-Price has not confined himself to a formal framework of subject matter, but has rather let his thoughts wander, he includes topics not often found in books on anaesthesia. There is one chapter, perhaps a little ambitious for any but the keenest nurse entitled 'Instructions on Anaesthetics for the Nursing Staff' another discusses the variations between Service and civilian anaesthetics. In such a small and inevitably dogmatic book there is bound to be much that will not meet with general approval but the reader will be indulgent in face of the author's pleasant literary manner and the publisher's praiseworthy production.

RECREATIONAL ACTIVITY

Recreation and the Total Personality By S. R. Shavson (Pp 205 53 00) New York Association Press 347 Madison Avenue N.Y. 17

The trend of the machine age is to increase leisure. With the increase of scientific achievement less and less manpower is required to produce the consumer goods necessary or convenient to civilized man. Unless there is to be wholesale unemployment each man must work shorter hours—and how is he to fill his spare time? Leisure activities must fulfil a felt want or compulsion in the individual but must also conform to the rules and dictates of society. By his recreation man must fulfil or find an outlet for instincts and impulses not otherwise satisfied, and he must so far as possible train himself in skills which will be useful to himself and to the community. Recreation to be effective must be fitted to the age, intelligence and social status of the leisured person. To this end there should be some intelligent planning of recreation, not so much with the idea of forcing any individual to adopt this or that recreational activity as to provide facilities so that every individual may have the opportunity to choose the amusement, game or hobby which appeals to him. Planning of this kind is a more serious matter in America than it is in this country and the present volume is a textbook for the planners of recreation. Clubs, recreational centres, and kindred organizations take themselves very seriously in the United States, and those concerned will find in this book how they may apply the lessons of physiology and social democracy and especially of mental hygiene in their programmes. To some it may appear that a great business is being made of play, but the reader will find here many fruitful suggestions and much sound advice not only for those who arrange for others to play but for the players themselves.

The Church Missionary Society has issued from 6, Salisbury Square, London, E.C.4, at the price of 1s 6d, a pamphlet entitled *Dynamics of Mercy*. This is an interpretation of recent CMS medical work by an anonymous author. There are reproductions of photographs and maps, and at the end a list of CMS medical missions in different parts of the world.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

The 1946 Year Book of General Medicine Edited by G. F. Dick, M.D., et al. (Pp 772 21s) Chicago The Year Book Publishers, London H. K. Lewis 1946

A summary of recent advances in medical science with many references to the literature.

Modern Clinical Psychology By T. W. Richards, Ph.D. (Pp 331 17s 6d) New York and London McGraw Hill Book Company 1946

An approach to psychological understanding of the personality from the point of view particularly of the psychoanalytic and derived schools. Intended for the intelligent layman as well as for psychologists.

Deep Analysis By Charles Berg, M.D. (Pp 261 12s 6d) London Allen and Unwin 1946

An account of the Freudian analysis of a single case. Intended for both doctors and laymen.

The Bacterial Cell By Prof. René J. Dubos (Pp 460 28s) Cambridge, Mass. Harvard University Press London Geoffrey Cumberlege 1946

Describes the physiology and structure of the bacterial cell and interprets the phenomena of virulence, immunity, and chemotherapy in terms of cellular organization.

Adolescent Sterility By M. F. Ashley Montagu (Pp 148 53 50) Springfield (U.S.A.) Charles C. Thomas 1946

An investigation into the period of infertility that normally follows the onset of puberty in man and other mammals.

Principles in Roentgen Study of the Chest By W. Snow, M.D. (Pp 414 51 0) Springfield (U.S.A.) Charles C. Thomas 1946

Correlates x-ray interpretation with the physical signs, symptoms and course of the disease. Profusely illustrated.

Our Inner Conflicts By Karen Horney, M.D. (Pp 250 10s 6d) London Kegan Paul, Trench, Trubner and Co 1946

This book is intended for the non-specialist as well as for psychoanalysts. It is divided into two parts: (1) Neurotic conflicts and attempts at solution, and (2) Consequences of unresolved conflicts. The author develops a theory of neurosis whose basic conflict is between the attitudes of 'moving toward', 'moving against' and 'moving away from' people.

An Approach to Social Medicine By John D. Kershaw, M.D., D.P.H. (Pp 329 15s) London Baillière, Tindall and Cox 1946

An examination of the structure of society and its bearings on human health and welfare, including wider issues such as the problems of genetics, sex, leisure, education, and food.

Clinical Hematology By Maxwell M. Wintrobe, M.D., Ph.D. Second Edition (Pp 862 55s) London Henry Kimpton 1946

Covers the whole field of haematology. Recent work considered includes the use of folic acid in pernicious anaemia, the Rh factor, the nitrogen mustard in the treatment of Hodgkin's disease, and the role of various vitamins in haematopoiesis. Many diagrams and illustrations, some in colour.

Penicillin in the Treatment of Infections By C. S. Keefer, B.S., M.S., M.D., and D. G. Anderson, A.B., M.D. (Pp 50 8s 6d) London Oxford University Press (Geoffrey Cumberlege) 1945

An outline of the uses of penicillin in medicine and surgery, with an account of its chemical characteristics and pharmacology.

Principles of Hematology By Russell L. Haden, M.A., M.D. Third edition (Pp 366 25s) London Henry Kimpton 1946

Intended for the student and physician. Blood disorders are regarded as disturbances in the normal physiology of the constituents of the blood rather than as true diseases. Bone marrow and the study of bone marrow films are described.

Diseases of the Heart and Circulation By A. A. Fitzgerald, M.A., D.M. (Pp 398 35s) London Oxford University Press (Geoffrey Cumberlege) 1947

An introduction to the study of cardiovascular disease for students and practitioners. Many illustrations.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 25 1947

THE COUNCIL'S RECOMMENDATION

The Council of the B.M.A. held a special meeting last week to receive the final plebiscite figures and in particular to consider the correspondence between the Presidents of the three Royal Colleges and the Minister of Health. The Presidents of the Royal Colleges have been criticized for intervening. Those critics who are strong individualists may on reflection consider their position is somewhat paradoxical in questioning the right of three prominent medical men to take an active part in seeking a solution of one of the most serious problems the medical profession as a whole has had to face. It would however serve little purpose to ignore the fact that the action of the Presidents has caused disquiet. Perhaps the chief reason for this is a general feeling that medico-political action is best taken by the organization whose job it is—namely the British Medical Association. The Royal Colleges are primarily academic institutions and the Presidents are elected to them because of their qualities as heads of such institutions. For them to enter the medico-political fray except as individuals is thought by many to place their colleges in a false position. Whether these objections will be sustained in calmer moments it is difficult to say, and however fiercely the Presidents may be assailed their professional colleagues must give them the credit for acting with the best of intentions and must at least admit that the intervention has drawn from the Minister of Health a statement which, while not offering much in substance is at least conciliatory in tone. The critics have their right to be heard and space has been given to them in the correspondence columns for this purpose. To put it at its lowest it would however be a tactical mistake if this episode were to be allowed to create a disunity in the profession, the Minister being a shrewd politician would wish for nothing better. Collectively doctors must recognize that there are sharp differences of opinion in their ranks but with that toleration which is supposed to be a British characteristic they must surely accommodate these differences within the framework of agreement on some fundamental issues. The first of these and one which at the moment there is a tendency to lose sight of is the need for a reorganization of the medical services in this country so as to provide the people with the best possible Health Service. The second—and this is a point on which there is only a small minority of disagreement—is opposition to the nationalization of medicine in the form of a State service.

The essence of the Minister's letter is his invitation to the profession to discuss the Regulations. Public opinion is expressed in newspapers of varying political colour considers the Minister has made a conciliatory gesture. For the medical profession to ignore this would put it

at odds with the rest of the community, even though the public shows little understanding of the doctor's case. The Minister's letter has, in fact, changed the situation which existed when the Council last met and made its recommendation to the Representative Body not to discuss with the Minister the Regulations under the National Health Service Act. We should be clear what this change is. It is one of atmosphere rather than of fact. The Council was fully aware that there was not much of substance in the Minister's letter other than a different attitude on the part of Mr. Bevan to the question of basic salary and his official recognition of the right of the profession to hold a further plebiscite which may end in a refusal to work under an Act complete with its Regulations and Orders. The Council's discussion of the Minister's proposal is printed in this week's *Supplement*. The view of the Council is best summed up in the words of the Chairman Dr. H. Guy Dain, as reported: "The Minister's offer was, in effect, an invitation to discuss with him on his terms within the structure of the Act the arrangements for carrying it out. His own view was that there could be no agreement to negotiate unless the discussions carried with them the understanding that if it were found necessary there would be further legislation to establish the principles to which the profession adhered but they were not willing to allow the Minister, having tied up his own projects in an Act, to talk with them only within that framework." Dr. Dain further remarked that the Education Act of 1944 had been quickly modified by an Amending Act. The attitude of Council was summed up finally, and with no dissent, by the following recommendation to the Representative Body which replaces the previous recommendation:

That the Association, having considered the final results of the plebiscite and the Minister's letter of Jan. 6 to the Presidents of the Royal Colleges and desiring to secure for the people the best possible Health Service, is willing that discussions be entered into with the Minister to that end provided that such discussions are comprehensive in their scope and that the possibility that they may lead to further legislation is not excluded that after the conclusion of these discussions a second plebiscite of the profession be taken on the issue of entering the Service.

The Council of the B.M.A. is therefore recommending the Representative Body to respond to the Minister's gesture of conciliation with a similar gesture. This is neither appeasement nor weakness. The recommendation is worded in plain language and means that the profession is willing to meet the Minister half way if he himself will meet them half way. The Council was not impressed with the Minister's attempt in his letter to suggest that he had negotiated the terms of his Act. It now asks him for a discussion which will include those features of the Act which the majority of doctors hold to be incompatible with a Health Service which would secure their willing co-operation. Mr. Bevan has the reputation of being an able politician with a remarkable gift of persuasive utterance. We hope he may seize the opportunity to show himself a statesman by responding to the profession's earnest desire to discuss clauses of the Act as well as the Regulations.

PAEDIATRIC PLANNING

The management and care of children in hospital is a subject which demands much more study than it has yet received. What work should be required of a children's hospital? What staff should it have? Is it possible to define, and fully to co-ordinate, the clinical, social, and supervisory responsibilities of doctors and nurses working in paediatric units? These are some of the questions posed, and answered, by Prof J C Spence in his Charles West Lecture, which appears in this issue at page 125. He stresses the need for the closest day-to-day co-operation between paediatric physicians and paediatric surgeons, between obstetricians and paediatricians, and between doctors and nurses and the mothers whom for many years he has been admitting to his own unit to assist in the care and nursing of their children. Recently J Tudor Lewis¹ asked for closer liaison between maternity units, hospital and home services, and public health departments as a means of preventing infant deaths following early discharge from a good maternity unit to a perhaps adverse home environment. For older children the risks of such an environment may be mitigated by attendance at a day nursery. The type of work undertaken at such a nursery is described in this issue (p 147) by Dr F M J Forsyth. On the other hand recent work² has shown an unduly high incidence of respiratory infection in children attending such nurseries.

Children present problems to their parents and their doctors from the moment of conception onwards. There are the social problems which range from those so vividly illuminated by the Curtis Report,³ which Prof Spence helped to compile, to those of the unstable adolescent girl.⁴ There are problems more purely medical, such as that of preventing cross-infection in children's wards, wards which may date back to Charles West or which may be E.M.S. huts specially adapted.⁵ Prof Spence has considered one problem, that of the proper care and management of children of all ages in hospital for long or short periods. His contribution should be read in the light of the report⁶ issued recently by the Paediatric Committee of the Royal College of Physicians of London. This report, to which much thought and care has been devoted over the past few years, outlines what is in effect a paediatric service for the nation.

Though paediatrics usually appears among the special subjects in medical curricula, there is no branch of medicine with wider associations and obligations, for it concerns itself with every aspect of health and disease during a particular age-period. It embraces, therefore, aspects of life which are not strictly or solely medical in the professional sense. Such influences as the educational status and economic circumstances of parents, housing conditions, opportunities for sound sleep and for recreation in suitable surroundings, conditions of school life, and many other environmental, social and economic factors take an important place in

paediatrics and must receive consideration and recognition in the child health service. There is, in fact, a real danger that the multiplicity of interests may result in a state of chaos. A co-ordinating and advisory authority is therefore needed, and this function will be best performed by men and women who hold a medical qualification, provided that their training has been planned to give them a sound understanding of both preventive and curative paediatrics. In the past these two aspects of the work have been separated by a gulf, which must now be bridged. The report deals at some length with this subject and expresses the view that the family general practitioner, armed with postgraduate training in the basic principles of public health as well as in prevention and treatment of illness in childhood, should continue in his role as the first line of defence. Working alongside him will be the hospital paediatricians and the "child health officers"—i.e., whole-time medical officers employed by local authorities. Now that institutes and departments of child health are springing up in many centres it should not be difficult to arrange for child health officers to maintain contact with curative paediatrics, and for hospital paediatricians to have opportunities for fuller experience in the prophylactic field. The Society of Medical Officers of Health has outlined a course of training suitable for child health officers; these recommendations are far-seeing and should be put into practice, with the addition of some experience in child psychiatry. All these proposals to broaden the experience and increase the interest of paediatric workers can be put into effect only if administrative medical officers and their committees are convinced that the general policy is a sound one.

The Committee's observations on hospital accommodation for children will be of special interest to the medical profession. It seems likely that England and Wales require some 23,000 beds for children suffering from acute illnesses excluding fevers, most of these beds will be in the cities or larger towns, but some should be in the long-term hospitals outside the cities and therefore available for acute cases in the surrounding districts. Every children's hospital should have an infectious diseases section, and every fever hospital should, so far as possible, be linked with a general children's hospital. Clinics and long-term hospitals for special categories of patients have an important place in the scheme, and units for the training of mothers would serve a useful purpose.

The quality of the training given to the available doctors and nurses is of fundamental importance, and the report rightly devotes some space to this subject. The institute and departments of child health are faced with heavy responsibilities and great opportunities which they will not be slow to accept, for their university status is assured. The necessary financial support is not likely to be withheld. Their influence upon the paediatric service will be measured not only by their contribution to teaching and research but by the service which their staffs will be able to render in an advisory capacity, granted the necessary provisions are made. The report suggests that in each region there should be a joint committee consisting of members of the university department of child health and the regional officers and local authority officers engaged in child health work, and that this committee should assist the Regional

Board by acting in an advisory capacity on all matters concerned with the health of children

The report is well balanced and maintains a proper sense of proportion and values. As evidence of this it should be noted, especially by those who are critical of any encroachments by the State upon the liberty and obligations of individuals, that the following sentence appears on page 1

Primary responsibility for the health of their children must continue to rest with parents, and they should regard members of the health services as agents helping them to carry out their duties and not as authorities taking the responsibilities off their shoulders

DOCTORS ON TRIAL

Twenty-three German doctors are now being tried in Nuremberg for crimes committed during the war. A photograph of the accused men appears above the first article by Dr Kenneth Mellanby on this subject at page 148 of this week's *Journal*. Dr Mellanby has been to Germany to collect first-hand information on this matter which is of profound significance in the history of medicine. It is a commonplace to say that medicine knows no frontiers, but behind this statement lies the recognition that medicine as it is practised in the civilized world is a product of Western civilization and therefore inspired by Christian ethics and Greek thought. The code of the civilized doctor is the Hippocratic oath. When therefore any group of medical men in a country claiming to be civilized offends against the spirit and tradition of Western medicine the offence becomes the concern of all doctors who follow the same tradition and try to live up to the same spirit. To ignore the infamy of those German doctors who have betrayed their trust and their profession would in part be to condone it. For this reason alone, therefore, we consider that the facts being disclosed at Nuremberg should go on record in the pages of a medical journal.

It was, we believe, Goering who said that Hitler was the keeper of his conscience. A glance at the diagrams in Dr Mellanby's article showing how medicine was controlled in Nazi Germany suggests how it was possible for some medical men to make the same error and fatal surrender—the surrender, in fact, of the individual conscience to the mass mind of the totalitarian State. It is probably impossible for the British doctor to understand the mentality of the German doctors accused of brutal experimentation on fellow human beings because he has not been submitted to a systematic degradation of human values over a period of 10 or more years. The question whether valuable information secured by such experiments should be used for the benefit of others has been discussed in the correspondence columns of our contemporary, the *Lancet*, in letters which show how difficult it is to look at such a problem in a dispassionate and objective manner. Dr S. M. Hilton¹ points out that 'valuable information has already been obtained by observation of victims systematically starved by their Nazi oppressors, yet no objection has been raised on moral, ethical, or political grounds.' Mr Denis Herbert² writes: "If their results are capable of being put to useful purposes and we destroy them we are ensuring that they have produced nothing but evil. If we publish and use them then at least some good will have followed." The situation might be summed up by posing this question: If in their experiments German doctors had discovered a cure for cancer would the rest

of the world say that this information must be destroyed because of the manner in which it was obtained? To say that such information should be used would surely not be interpreted as condoning the method or as encouraging others to pursue similar methods.

HIGH UP IN THE KITCHEN

Communal feeding for all grades of society has probably come to stay in our country as it has in America. Food rationing, shortage of domestic help and difficulties in travel have led to an increasing proportion of 'meals out' while works and school canteens have multiplied a thousandfold during recent years. This communal feeding must increase the risks of food borne infection unless the highest hygienic standards are maintained in the kitchen and the steady rise in the number of reported outbreaks of food poisoning during the war years,¹ from 47 in 1940 to 550 in 1944 reflects in some measure the present dangers from the communal meal. While a fair number of these outbreaks have been due to contamination of food with intestinal pathogens of the *Salmonella* and dysentery groups, a large proportion have been clinically and epidemiologically, examples of toxic food poisoning such as is caused by the enterotoxigenic *Staphylococcus* but may also be due to other less well differentiated bacteria. Indeed there is bacteriological evidence that any gross bacterial contamination of food may result in an outbreak of gastro-enteritis.

The main sources of bacterial contamination are the hands of the kitchen staff and the utensils used for handling and holding food. Food that has been cooked and is properly stored overnight—and cold storage is often lacking or inadequate—is a particular danger since such food acts as a culture medium for bacteria from hands or utensils. The danger from the latter source is well exemplified by the bacteriological examinations of crockery and cutlery in a variety of restaurants recorded in our present issue by Dr Irene Hutchinson. Of a large selection of spoons, cups, forks, plates and glasses swabbed after they had been washed and stacked she recovered *Staphylococcus* from 3-12%, haemolytic streptococci from 1-4% and coliform organisms from 20-40% of the utensils while *Str. faecalis* and *Str. viridans* indicators of faecal and salivary contamination respectively were present in a high proportion of the examinations. The Sonne dysentery bacillus was once isolated from a spoon. No mention is made about bacteriological examinations of larger cooking utensils or containers but the fact that 50% of 38 dish-washing waters that were examined gave counts of one million or more bacteria per ml. growing at 27°C suggests that kitchenware generally would be heavily contaminated. The consequent risk to improperly stored food is obvious. Whether crockery and cutlery carrying respiratory pathogens such as *Staph. aureus* and haemolytic streptococci are likely vehicles for the spread of infection by these organisms would be difficult to prove, perhaps the risk is greater with certain respiratory viruses which can infect in very small dosage. But the thought that the crockery and cutlery served with a meal may still harbour the bacterial flora of a previous user must be repugnant to all, and for both hygienic and aesthetic reasons measures are urgently needed to improve kitchen hygiene.

The greatest need is for education of the food handler. Much progress has been made along this line in America where health authorities have found restaurant proprietors and staff very willing to be educated in methods for avoiding or minimizing food contamination. In this country

¹ *Lancet* 1947 1 31
² *Ibid.* 1947 1 84

³ See the Report of the Chief Medical Officer, Ministry of Health, *Control of the Public Health Duties of the Food Service*, 1947.

courses of instruction on food hygiene for food handlers are about to be begun on a large scale under the auspices of the Central Council for Health Education.² The present plan is to give a course of three lecture-demonstrations to key personnel in catering establishments and to follow up this intensive course with simpler instruction to kitchen staff, waitresses, and the like. Too often, however, the menial work of washing up in the kitchen is done by staff of low educability, and here the need is for better conditions and wages to attract more intelligent workers. The educational programme should be supplemented by increased powers of supervision by the Medical Officer of Health and his sanitary inspector, who at present have no right of entry into catering establishments except to inspect the premises where food is prepared and sold and to ensure that washing facilities are available. Indeed, the existence of most factory canteens comes to the knowledge of the Medical Officer of Health only indirectly, for local authorities are not compelled to register them.

Facilities for dish-washing and for cold storage of food, particularly prepared food, need to be greatly improved. If crockery and cutlery are to be properly cleaned and freed of bacterial pollution they must, after removal of food residues, be washed in water at 120–140° F with a suitable detergent, of which there are now many on the market. They should then be transferred to a separate sink and rinsed, preferably in wire-mesh containers or racks, at a temperature of 170° F for two minutes. They could then be drained, allowed to dry without wiping, and stored in a covered cupboard. The wash water must of course be changed frequently, and if cloths are used for wiping they should be boiled daily. Mechanical dish-washers with separate washing and rinsing compartments do the job much more efficiently than the human hand and at a considerable saving of labour. Such dish-washers are being made in this country, and no doubt large catering firms who have had experience of them can help manufacturers to improve design and also advise smaller firms about their availability and uses. The kitchen itself should be large, with plenty of cupboards and cold storage, well lighted and ventilated, with walls and floors that can be easily washed, and preferably in full view of the customers, so that everyone may know that the food they eat is being prepared and served under the best hygienic conditions.

GYNAECOMASTIA

Many who served as medical officers in the Armed Forces will have encountered cases of enlarged or painful breasts in males. This relatively mild disability attains a greater importance in Service life, for the sufferer is liable to be exposed to the ridicule of his fellows and to become ashamed of his abnormality, and webbing equipment may rub on the swollen breast causing discomfort or even considerable pain, a point which, it is interesting to recall, was observed as long ago as 1868. A full review of the condition as it was encountered in the United States Army, where the frequency was about 16 per 100,000 men, has recently been published by Karsner,³ who had access to the records of 284 cases.

By true gynaecomastia is meant a swelling due to hyperplasia of breast tissues occurring in the male, and it has to be distinguished from a mere deposit of fat in the breast region. The hyperplastic mammary tissue can be felt as a firm button or plate-like mass under the nipple. It does not usually adhere either to the nipple or to the deep structures. In the great majority of cases the condition is

unilateral, both breasts being involved in only twelve of Karsner's cases. The two sides are affected with about equal frequency. The weight of the abnormal tissues when excised varies from 25 to nearly 400 grammes, the mass consisting of a proliferation of connective tissue together with an increase and often a proliferation of duct tissue. The secretion that sometimes distends the ducts is probably a mucinous substance and not strictly comparable to colostrum. Acini and lobules are not formed. Some inflammation is usual in these tissues, but it is not closely related to the degree of tenderness complained of. No tendency to neoplasia was seen in any of Karsner's series.

The cause of the condition is still a matter for speculation. The majority of the cases are probably primary in the sense that the abnormality originates in the breast tissue itself. The fact that most cases are unilateral does not exclude an endocrine factor (exophthalmos may be unilateral in hyperthyroidism), but in only a small proportion of the cases was there any evidence of endocrine abnormality. Occasionally a testicular neoplasm was present. Karsner found seven such tumours—two embryonal carcinomas, four malignant teratomas, and one chorio-carcinoma. In such cases there is a large production of chorionic gonadotrophin, which may well be an aetiological factor, though satisfactory proof is lacking. The rare adrenal cortical tumours may cause gynaecomastia and it has also been observed after treatment with adrenal cortical extract and with desoxycorticosterone acetate. Oestradiol and stilboestrol may cause it in man. In most cases, however, there is no evidence of disturbed production of any of these hormones, and the gynaecomastia may be attributed to an unusual sensitivity of the breast tissues to hormones circulating in almost normal quantity.

The treatment of the condition is surgical removal of the breast tissue if pain or anxiety is being produced by it. Endocrine therapy has no consistent beneficial influence on the swelling.

PROGNOSIS OF HYPERTENSION

When queues begin to form for the surgical treatment of hypertension the moment is propitious for reviewing the natural history of the disease. The publication of Bechgaard's extensive monograph¹ dealing with a detailed eleven-year follow-up study of more than 1,000 cases of hypertension is therefore timely. The material is well handled and presented and the literature conveniently reviewed (there are 269 references). The cases were taken from the out-patient polyclinic of the Rigshospitalet in Copenhagen, and of the total number of 1,038 hypertensives as many as 1,002 were successfully traced. By hypertension was meant a blood pressure of not less than 169/90, the average was 190/110 taken after 15 minutes' rest. The majority were cases of essential hypertension, only 13% being malignant and not more than 20%, and probably far less, being renal. There were 325 men and 713 women, but the overall ratio at the clinic was 3/2 in favour of women. They were mostly of the working classes. Of the malignant group none were due to a unilateral "surgical kidney."

The sex incidence for malignant cases was 3/1 in favour of men (cf. Volhard 5/1, Ehrstrom 3/1, and Page 2/1—all cited). The importance of heredity as a aetiological factor was shown by the calculation that the incidence of hypertension among the parents must have been about 75% (cf. Ayman² and Hines³).

² *Health Education Journal* Jan. 1947 p. 11.
³ *Amer. J. Pathol.* 1946 22 235.

¹ *Acta med. scand. Suppl.* 1946 172 269.
² *Arch. intern. Med.* 1934 53 792.
³ *Proc. Mayo Clin.* 1940 15 145.

The mortality rate was twice as high in men as in women for all age groups if cases of renal hypertension were excluded. It was not adversely influenced by obesity—rather the reverse—nor by the height of the blood pressure, provided that it was below 200/130 in men and 220/130 in women, but it was doubled if there was evidence of hypertensive heart disease. The death rate for all cases of high blood pressure expressed as a ratio of that of the general population of Denmark was 2.88:1 for men and 1.43:1 for women, the death rate in renal hypertension expressed in the same way was 18:1. Over the 4-11-year period 41% of the men and 22.4% of the women died. The cause of death was cardiac in 45%, cerebral in 16%, and renal in 10%. The group is comparable to those studied by Janeway⁴ and Blackford, Bowers, and Baker,⁵ and on the whole the conclusions are similar. Statistics taken from hospital in-patients with hypertension are less favourable.

In the follow-up examination 13% of the men and 2% of the women had regained normal blood pressures. Of 78 women who might have been diagnosed as cases of menopausal hypertension at the first examination, none regained normal pressures, nor did the graph of age incidence show the least tendency to a peak at the climacteric. During the period specified 0.2% of those with essential hypertension and 8% of those with chronic pyelonephritis entered the malignant phase.

These various facts suggest that lumbo-dorsal sympathectomy might be reserved with advantage for males with blood pressures of 200/130 or above, and for females with blood pressures of 220/130 or above, but the males should not be expected to do more than half as well as the females. The tendency to deny operation to obese females on technical grounds is supported now on a prognostic basis. Hypertensive heart disease far from being a contraindication to surgery, would appear to be an added inducement especially as it may be reversible (Paul White 1946).

L ORGANISMS IN GENITAL TRACT

Organisms of the pleuropneumonia group, conveniently called L organisms, are comparatively widely distributed, and many of the species are pathogenic for animals, especially cattle and rodents. Their presence in the genital tracts of men and women has been reported by Dienes,⁶ Dienes and Smith,⁷ Beveridge,⁸ Klieneberger-Nobel,⁹ and by Salaman.¹⁰ Beveridge, Campbell and Lind¹¹ isolated these organisms from 20% of male patients with non-specific urethritis, and complement-fixation tests were positive in over two-thirds of sera tested, they also found them in 17% of women attending a gynaecological clinic and state their belief that non-specific urethritis, which was relatively common in the Australian Forces, was in the majority of cases due to them.

Salaman¹² has carried out an investigation in a British military hospital and cultured L organisms in males from twelve out of thirty-five cases of gonorrhoea, three out of forty-five cases of non-specific urethritis, two out of thirty-four cases of residual non-specific urethritis after gonorrhoea, and from three out of twenty-four cases without signs of genito-urinary disease, and in females from eleven out of eighteen cases of gonorrhoea, thirty-nine out of sixty-three cases of trichomonial vaginitis, eight out of

eighteen cases of non-specific cervicitis, twenty out of twenty cases of gonorrhoea and trichomonial vaginitis, six out of eight cases of non-specific cervicitis and trichomonial vaginitis, but from only one out of seventeen clinically normal women. These results are not very conclusive but what is remarkable is that he was able to detect L organisms by means of penicillin, which inhibited gonococci but not L organisms, in each of eighty strains of gonococci that he examined.

These organisms were found to grow well on 10% chocolate agar in an atmosphere of carbon dioxide, they were demonstrated by cutting out pieces of the medium placing them face downwards on a slide and fixing and staining by a special process. They are intermediate between bacteria and viruses and under the microscope appear as a framework of very fine filaments in the meshes of which are clusters of vesicles 2-10 microns in diameter containing tiny granules. Salaman offers four possible explanations. L organisms (1) may be degenerative forms of gonococci, (2) may invariably contaminate strains of gonococci, (3) may live in symbiosis with gonococci or (4) may be stages in the life cycle of gonococci. The last possibility is very attractive especially in view of the difficulty of demonstrating gonococci in chronic and complicated gonorrhoea. Nevertheless much more work needs to be done before any definite conclusions can be drawn.

EPIDEMIC KERATO-CONJUNCTIVITIS

The concept of epidemic kerato conjunctivitis has clarified ideas on various obscure conjunctival and corneal lesions. Different aspects of this protean affection have been recognized in the past as the designations superficial punctate keratitis, macular keratitis, nummular keratitis, keratitis subepithelialis, and many others testify. That trauma is probably a factor is suggested by the name of shipyard keratitis and the localities of epidemic outbreaks seem to implicate the sea-coast in the chain of causation. Clinically the significant features of the disease are its great infectivity, the involvement of the pre-parotid lymph nodes, the prolonged course, the serous nature of the conjunctival reaction with disproportionately heavy symptoms, the absence of bacteria in the conjunctival secretion, and the variegated corneal lesions. Pathologically there is much to support the work of Sinders who isolated a filter-passing virus. The condition has proved resistant to treatment.

Epidemics of kerato conjunctivitis have been noted in recent years in widely scattered parts of the world. Apart from the severe epidemic on the Pacific coast of the United States and subsequently on its Atlantic coast there was an epidemic in 1937 in the Middle East persisting for several years, and apparently one in Germany in 1940. The German epidemic seems to have been sufficiently severe and protracted for the Swiss authorities to promulgate special measures for the protection of their armed forces in June, 1945—a measure regarded as panicky by Rintelen.¹ Of the epidemic in the Middle East Feigenbaum, Michaelson, and Kornblith² have contributed a valuable study based on material observed in Palestine. Like other observers they stress the roles of trauma and ill defined climatic factors, like them, too, they failed to find inclusion bodies in epithelial scrapings. Though they do not go as far as Wright in speaking of keratitis diversiformis, they stress the great variety of corneal reactions, which consist mainly of ill defined subepithelial dots. There are, however, also definite subepithelial infiltrates, or superficial epithelial infiltrates, and more rarely disciform keratitis.

The conjunctival reaction they observed was also variable and must be regarded as the primary lesion, though corneal involvement existed in well over half the cases, there may be a non-specific congestion, velvety reaction, or follicular hypertrophy simulating trachoma. Histological examination of human conjunctiva showed flattening of the epithelium, marked capillary dilatation, oedema in the subepithelial tissue, and subepithelial infiltrates with lymphocytes and large mononuclear cells. They could confirm the specific infective nature of the disease by rabbit experiment, while by tissue culture and filtration experiments they, like Sanders, found the infective agent was a filterable virus. In contrast to the immunity seen in patients and shown by immune tests none is developed by the rabbit.

A further contribution on epidemic kerato-conjunctivitis, as seen in the Middle East, has been made by O'Donovan and Michaelson³ on cases in Egypt. Here a striking aspect was an associated skin lesion—mainly seborrhoeic dermatitis involving the scalp and face. To what extent this association is parallel to that found in herpes simplex and zoster they leave an open question.

RELIEF OF ITCHING AND URTICARIA

In 1937 Bovet and Staub⁴ detected anti-histamine activity in certain aromatic derivatives of amino-ethyl and ethylenediamine, and since then much progress has been made. The obvious field of application is in allergic conditions in which histamine—or H substance—probably plays an essential part. Efficient anti-histamine substances should relieve allergic manifestations and may lead eventually to a better understanding of allergy. According to Mayer the mechanism of action of these substances is unknown, and the idea generally accepted at present is of a competition with histamine analogous to the displacement of *p*-aminobenzoic acid by the sulphonamides.

Over eighteen months Brack⁵ tested upon over a hundred skin cases an anti-histamine substance 2(*n*-phenyl-*n*-benzylaminomethyl) imidazolin, marketed as "antistin". He has found it is possible with suitable dosage to diminish or abolish the irritation in all cases of urticaria, eczema, neurodermatitis, prurigo, lichen ruber planus, psoriasis, nervous pruritus without cutaneous changes, and post-scabietic itching. In urticaria the rash can be relieved or suppressed, but in the other skin conditions mentioned no direct effect on the disease is obtainable, though relief of the itching helps considerably. In some cases, perhaps by breaking a vicious circle, complete cure results, but as a rule and where the underlying cause is still operating, the duration of the action of "antistin" is essentially temporary. That it acts peripherally on the vasomotor system is shown by the effects of local application in scratch tests with histamine, diethylmorphine, and simple trauma, when suppression of itching and reduction in the weal size always obtain.

"Antistin" can be given orally (0.1 g tabs), intramuscularly, or intravenously (0.1 g in 2 ml). Success in treatment depends largely on finding the suitable dose. The initial dose should be small and intravenously 0.1 g should be given very slowly over five minutes. The only common unpleasant side-effect is transitory faintness or giddiness, which requires a reduction in oral dosage or of speed of injection. Brack points out that the patients themselves often limit the dosage after getting such attacks. Some patients ask if they have been given a strong hypnotic, and this action of "antistin" is attributed to the effect of the

relief of itching in an exhausted patient, though a central effect is not yet disproved.

This observation is of special interest in view of the drowsiness which often occurs with "benadryl" (β dimethylamino ethyl benzhydryl ether hydrochloride), another new anti-histamine substance recently synthesized. Curtis and Owens⁶ have tested this drug in eighteen patients suffering from chronic urticaria which was completely controlled, in all but four cases, so long as the patient continued treatment, but it recurred immediately the drug was withdrawn. Doses of 50 mg, given three times a day, produced relief within two hours in most cases, but many complained of a feeling of drowsiness, and in one case there were severe weakness and vertigo, which passed off on stopping the "benadryl". Shaffer, Carrick, and Zackheim⁷ have also used the drug in ordinary urticaria, in papular urticaria of children, and in eczema. Their findings in urticaria are similar to those of Curtis and Owens. Only a few cases of strophulus and eczema were treated, but the drug did not appear to be of great value in these conditions. They noted that the maximum response to the drug occurred twenty to sixty minutes after oral administration and lasted for five to eight hours. "Benadryl" controls the pruritus and temporarily clears the eruption in urticaria, and it is suggested that it may be usefully administered in chronic cases while appropriate investigations are being conducted.

SCOTTISH DOCTORS RESIST

The movement for a closed shop for doctors has spread to Scotland. On Jan 7 the Motherwell Town Council passed this resolution:

That as from and after Feb 1, 1947, it shall be a condition of employment or continued employment in the Departments of the Town Council, or any of them, that every employee shall be or shall have become a member of the Trade Union appropriate in his case.

A minority of the Council was opposed to coercion or applying the condition to existing employees who are non-unionists. Baillie Welch moved the above motion on behalf of the Labour Group of the Council and in face of a communication from the Department of Health for Scotland which ended thus, "while the Secretary of State is anxious that doctors, nurses, and members of similar professions should join a trade union or appropriate professional association he considers that this matter should not be determined by the unilateral action of local authorities." The Scottish Secretary of the B.M.A. immediately drew the attention of the Town Clerk of Motherwell to the opposition of the B.M.A. to the imposing of such condition of employment on members of the medical profession. At the same time he was assured by the Secretary of the Scottish Branch of the Royal College of Nursing of the co-operation of the Scottish nurses in any action they might take. Eight medical men holding part-time appointments with the Motherwell and Wishaw Town Council immediately tendered their resignations, stating in a resolution that they had no intention of joining a trade union or professional association at the dictation of the Town Council. These Scottish doctors also observed that the Town Council had broken their contracts by introducing a new condition of service without giving the necessary three months' notice.

Medical men in England will applaud the prompt action of protest on the part of their Scottish colleagues. It is only by such action that the present epidemic of dictators will be brought to an end.

WORK AT A DAY NURSERY

BY

F M V FORSYTH, M.B., Ch.B.

This is a report of the work done at a day nursery (Battersea Central Mission) from September, 1944, to December, 1945, during which time 60 children between the ages of 2 and 5 years attended. The nursery is situated in a poor district in South London, and suffered a fair amount from 'buzz-bombs' and rocket bombs. The work can be classified under three headings: (1) preventive medicine, (2) social and psychological medicine, and (3) treatment of minor ailments and injuries.

Preventive Medicine

Our lines of attack in prevention are the three usual ones: maintenance of general health, early isolation, and immunization or similar active measures. The record for infectious diseases over the period under review is as follows:

Complaint	No. of Cases	Time of Occurrence
Measles	10	Feb. 1945 3 cases; March and April 1945 7 cases
Mumps	1	June 1945
Chicken pox	7	July 1945 1 case; Sept. 1945 6 cases
Whooping-cough	3	Oct. 1945
Scabies	3	Sept. 1945—two of these were brother and sister
Impetigo	1	
Scarlet fever	(secondary to scabies)	
Diphtheria	None	
Gastro-enteritis		

Maintenance of General Health—(1) All children have to present a doctor's certificate recommending their admission to the nursery and also after being away sick with any infectious condition. (2) New entrants are medically examined on admission. (3) Routine medical examinations are made at frequent intervals, with weighing. (4) The diet is balanced with an adequate vitamin intake (Ultra violet light and carbon arc and mercury-vapour lamps are available in the physiotherapy department). (5) A rest period is arranged, and there is a regular routine. It cannot be sufficiently emphasized that our children would not have a regular routine, discipline, or proper meals in their own homes. The usual diet would be bread and jam, chips, or ice-cream, taken when hunger or fancy dictated, and eaten in the street in all probability. Their priority oranges and eggs are often sold to adults or given away to sick friends. Even toddlers play in the streets on their own until late at night—without any rest during the day. A fair number, through absence of training, wet themselves during the day up to 4 or 5 years, and at night up to 7 years.

Early Isolation—The matron has had much experience in fever hospitals and quickly notices any child that is 'off colour', it is put in the isolation room at once. All children's hands are inspected for lice on arrival and 'spots' are also looked for. The fact that we have had only 3 cases of scabies in 60 children over a period of 15 months is proof of her efficiency.

Active Measures—(1) No child is accepted now for the nursery unless it has been immunized against diphtheria within two years, or its parents agree to our carrying out immunization or reimmunization at once. The children were Schick tested before reimmunization in November, 1944, but this year owing to the occurrence of a few cases of diphtheria in the district, all those nearing the end of the two years were promptly reimmunized. So far we have not Schick-tested the children following immunization. (2) We recommend vaccination when it has not been done, but do not insist as in the case of diphtheria immunization. (3) Patch tuberculin tests are carried out on any child that is not doing well. Nine children tested were all negative and gained well after a course of ultra-violet ray treatment. We hope to make a routine patch test on new admissions in the future. (4) Through the courtesy of the L.C.C. Southern Group Laboratory we were able to give 10 ml. of adult measles serum to each of 13 children during the measles epidemic of January-April, 1945. We had no

reactions. The children selected were the youngest and most delicate of those who had not already had measles. Only one child of the 13 contracted measles. This was a mild attack, occurring 9 weeks after injection in a delicate only child subject to bronchitis. The medical officer of health for Battersea informs me that 1,029 cases were reported for the district from Jan. 1 to March 31, 1945. We had eight cases amongst our 60 children in the same period—38 of the children had not had measles before. (5) In October, 1945, following two cases of whooping-cough in the nursery, I carried out a series of whooping-cough inoculations. Four children had the combined whooping-cough vaccine and APT in the usual dosages at weekly intervals except for the fourth dose which was given one month after the third. Nineteen children had slightly increased doses of the standard A' whooping-cough vaccine (Parke Davis 4,000 million Bordet's per ml.). In view of the much larger doses used in America the doses given were 0.75, 1, 1.25, and 1.5 ml. In four of these 19 local swelling and redness followed the second dose and in each case the child was 3 years old. In these four cases the remaining doses were kept at 1 ml., and there have been no reactions. Up to date only one case of whooping-cough has developed and that in a child who had a cough at the time of inoculation. The case was severe, one complicated by bronchopneumonia. The interval between the first three doses was three days. The fourth dose was given three weeks after the third.

Social Medicine

From September 1944 until August 1945 we had in the nursery two mentally defective children—brother and sister. The boy, aged 5 years, had been unable to speak, and his mother had been advised to send him to the Fountain Hospital as a hopeless case. The little boy was of an affectionate disposition, and became able after some months in the nursery among normal children younger than himself to say one or two sentences and to make very good efforts to get himself understood. During the war we could find no speech clinics which could take him and we did not have sufficient staff to give him individual training or exercise lessons. The matron, however, trained him to put out the cups and plates for tea and to collect the dirty things after a meal. His star sentence became, 'Can I collect up the cups?' but it needed a little skill to understand him. The teacher also discovered that he had an excellent sense of rhythm and could beat in time to music. He is of course now attending a special school under the new Act. The sister, aged 3 years, also mentally defective, could speak, but we could not establish as much contact with her. Her twin was normal.

Conclusion

Day nurseries are of supreme importance in improving the health of the coming generation and form a link between the infant welfare clinic and the school clinic during the important years between the ages of 2 and 5 years. Those who are the only child and mild mentally defective cases benefit greatly from contact with other children and from expert handling by a trained staff.

The *Year Book of Radiology* is now so well established that the 1945 edition needs no introduction to the radiological world. As before, it has as editors C. A. Waters and W. B. Farrow in diagnosis and I. I. Kaplan in therapy. Each subject occupies about half the book. The diagnostic half contains references to many articles of importance. In the section on bones and joints articles of note are those on stress fractures of the 1st rib by Alverson and others; Significant Skeletal Changes in the Hand by Holt and Hodges; and one by Holmstrom of Sweden on free fat in the knee joint after injury. From the Mayo Clinic comes a report on six cases of Albright's disease. Lloyd Rusby's important review of 246 cases of dermoids and teratomas of the mediastinum receives due prominence as does O. A. Nelson's interesting work on angiography of the abdominal aorta. In the same section is Baker and Miller's account of 100 consecutive cases of angiography of the lower limbs. The section on radiotherapy again gives a comprehensive account of recent work in the various branches of this subject, including radiobiology. The 1945 yearbook (H. K. Lewis and Co. '6s.) well maintains the high standard set by its predecessors, and will be valued by all who are fortunate enough to obtain a copy.

MEDICAL EXPERIMENTS ON HUMAN BEINGS IN CONCENTRATION CAMPS IN NAZI GERMANY

BY

KENNETH MELLANBY, OBE, ScD

Reader in Medical Entomology London School of Hygiene and Tropical Medicine

The present trials of many German doctors and medical administrators before Military Tribunal I of the United States of America at Nuremberg has drawn public attention to the vast number of human experiments, many of which proved fatal to the victims, which were carried out on prisoners in concentration camps. This trial is not yet over and many more trials of a similar nature are likely to take place in the near future, it would therefore be improper at this time to discuss in any detail the personal responsibility or guilt of any of the defendants since the matter is still *sub judice*. However, many points have already been clearly established, and a picture of the organization and conditions which made these actions possible can be given.

Some people in this country have suggested that the accounts which they have read of these experiments, and of conditions in concentration camps generally have been wilfully distorted as propaganda in order to intensify hatred against Germany. It has even been suggested that few or even no experiments of an objectionable nature ever took place. The fact of the experiments was clearly proved by the International Military Tribunal which tried Goering and his colleagues. The judgment of the IMT states:

'The inmates [of concentration camps] were subjected to cruel experiments victims were immersed in cold water until their body temperature was reduced to 28° C, when they died immediately. Other experiments included high altitude experiments in pressure chambers experiments to determine how long human beings could survive in freezing water experiments with poison bullets experiments with contagious diseases, and experiments dealing with sterilization of men and women by x rays and other methods'. There are many references to these and other experiments in the judgment and to the responsibility of the various Nazi leaders and organizations. There is no doubt that thousands of individuals were the involuntary victims of medical experiments and that a high proportion died. Many more died as a result of medical neglect or improper treatment. Finally, thousands of prisoners were put to death by methods

devised and executed by physicians engaged in 'research' into the problem of killing as rapidly and expeditiously as possible.

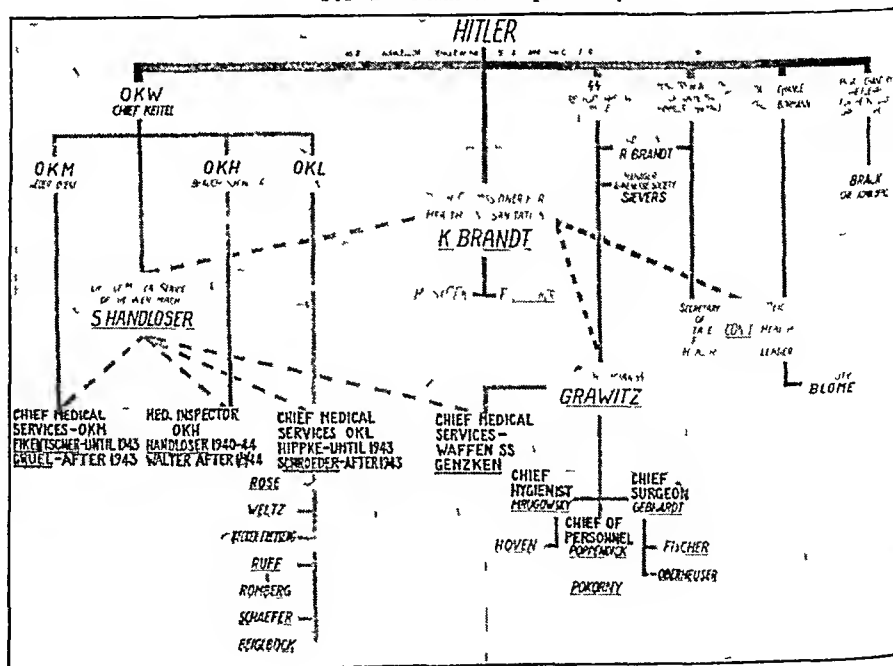

The Punishment of War Crimes

Before the end of the war the Allies resolved that after victory those members of the Axis Powers who had been guilty of war crimes should be made to pay the penalty and they established an elaborate mechanism to ensure this. In Germany the International Military Tribunal representing Britain, France, Russia, and the United States was set up to try the

leaders of Nazi Germany who were deemed to have the major responsibility for the crimes which caused the war and which accompanied hostilities. While this tribunal was still sitting each of the four occupying powers set up its own military tribunals to try the 'lesser fry'. Long before the IMT had reached its decision the other tribunals had completed numerous cases, acquitting some defendants, convicting others and sentencing them to death or imprisonment. It is intended that a uniform standard of justice should be maintained by all powers.

Defendants have already been convicted and executed for carrying out medical experiments. Thus at Dachau early in 1946 Dr Klaus Karl Schilling, the eminent malarialogist was hanged for his part in experiments in which some 1200 prisoners were infected with malaria. He had a greater claim than most of the experimenters to the title of scientist. He went to Dachau on the invitation of Himmler to carry out experiments in malaria on which subject he was a well known authority (he had been a member of the League of Nations Malaria Commission). He was over 70 when these experiments were carried out. Believing that the experiments would provide an unequalled opportunity for the advancement of malarialogy he used a mild strain of benign tertian malaria which would be unlikely to prove fatal in healthy individuals, and he himself appears always to have administered drugs carefully and scientifically. He is said usually to have obtained the consent of the prisoners before he infected them, but at Dachau this could not amount to very much. He was accused at a trial held by the U.S. authorities of having caused many deaths. The Court took the view that although Dr Schilling's motive may have been sincere and purely a scientific one his activities exemplified the Nazi schema which existed at Dachau. The

FIG 2—Chain of Responsibility

part he played in that schema is clear. Quite a number of other medical research workers, some of whose names have been mentioned in evidence at the present Nuremberg trial are under detention awaiting examination before American, British, French or Russian tribunals. It is a pity that the existence of these other tribunals is so little known. They are doing a difficult and thankless job often revealing facts of great interest and importance about medical experiments and other activities.

Key to Fig. 1

It is a little difficult to give briefly a clear statement of the legal basis on which these various tribunals operate, and some eminent jurists feel that the situation is unsatisfactory and may lead to serious abuses. The tribunals do not work strictly according to the legal code of any country. They follow the laws as set forth by the Allied Control Council in 1945 and they attempt also to abide by decisions and resolutions of various international conventions such as that signed at The Hague in 1907. The laws of evidence are as a rule rather liberally interpreted and as a result much time is spent in wrangling between the opposing counsel as to the admissibility or otherwise of affidavits and other documents. My own impression is that the various tribunals do in fact preserve a proper judicial impartiality and make every effort to give all the defendants a just hearing.

The Indictment

The twenty-three defendants at present on trial at Nuremberg are all charged on three specific counts, and ten of them face a fourth charge. The charges are as follows: I. The common design or conspiracy. II. War Crimes. III. Crimes against humanity. IV. Membership of a criminal organization (this applies to the ten members of the SS).

To the non legal mind the first three charges are very confusing, for they all refer to various aspects of the same activities. It is under Charge II War crimes, that the various medical experiments are given in detail and the particular responsibilities of the different defendants are listed. The experiments which will be dealt with in more detail in a later article, concern toleration of high altitudes, resistance to freezing, malaria infection, mustard gas, treatment with sulphonamides and other substances of artificially inflicted wounds, the regeneration of tissues in artificially inflicted wounds, the potability of sea water, epidemic jaundice, methods of sterilization, epidemic typhus, effects of poison, the treatment of burns by incendiary bombs. Further crimes consist of the murder of 112 Jews to

produce a skeleton collection and the various euthanasia programmes for removing scores of thousands of Poles with tuberculosis and millions of 'useless eaters'.

Brigadier General Telford Taylor, of the U.S. Army, chief counsel for the prosecution made the various issues clear in his opening speech. He stated that 'the defendants are charged with murders, tortures and other atrocities committed in the name of medical science. The victims of these crimes are numbered in hundreds of thousands'. He then stated that the prosecution did not merely wish to punish the guilty for their part in these atrocities, but that 'it is far more important that these incredible events be established by clear and public proof, so that no one can ever doubt that they were fact and not fable, and that this court, as the agent of the United States and as the voice of humanity, stamp the ideas which engendered them as barbarous and criminal'. The essential point was to show how 'the poison of Nazi doctrine' had so corrupted men 'exceptionally qualified to form a moral and professional judgment' that they were capable of these acts. It was necessary to demonstrate clearly that it was not a few sadistic criminals who were responsible but that the whole body of organized medicine in Nazi Germany was behind the policy.

The Defendants

There are at present twenty three defendants in the dock at Nuremberg (see photograph on p. 148). Of these twenty are medical men of one kind or another and three were concerned with the administration. These defendants are, however, by no means the only Germans who might have been indicted. The IMT made it clear that these medical crimes were part of the general policy of the Nazi leaders. Hitler knew about them and gave his approval and encouragement. But of the better known leaders it is Heinrich Himmler, *Reichsführer* of the SS and later also Minister of the Interior, who was particularly concerned. Himmler climbed the gallows by committing suicide, but his obsessional character made him retain every letter

memorandum, and report even including scraps of paper with rough notes on them. These documents clearly established his paramount role. He was not himself a scientist, but he took a considerable, though quite uninformed interest in research. In medical investigations he was constantly urging others on to produce immediate practical results irrespective of the brutalities which might be inflicted. This constant urging from above that 'practical results must be forthcoming together with the general unscientific temper of the environment' did much to ensure that the experiments were of the minimum scientific value.

Few of the defendants are accused of actually carrying out the experiments themselves, they are mostly the responsible organizers alleged to have planned the

MEDICAL EXPERIMENTS ON HUMAN BEINGS IN CONCENTRATION CAMPS IN NAZI GERMANY

BY

KENNETH MELLANBY, OBE, ScD

Reader in Medical Entomology, London School of Hygiene and Tropical Medicine

The present trials of many German doctors and medical administrators before Military Tribunal I of the United States of America at Nuremberg has drawn public attention to the vast number of human experiments many of which proved fatal to the victims which were carried out on prisoners in concentration camps. This trial is not yet over and many more trials of a similar nature are likely to take place in the near future, it would therefore be improper at this time to discuss in any detail the personal responsibility or guilt of any of the defendants since the matter is still *sub judice*. However, many points have already been clearly established and a picture of the organization and conditions which made these actions possible can be given.

Some people in this country have suggested that the accounts which they have read of these experiments and of conditions in concentration camps generally have been wilfully distorted as propaganda in order to intensify hatred against Germany. It has even been suggested that few or even no experiments of an objectionable nature ever took place. The fact of the experiments was clearly proved by the International Military Tribunal which tried Goering and his colleagues. The judgment of the IMT states:

The inmates [of concentration camps] were subjected to cruel experiments victims were immersed in cold water until their body temperature was reduced to 28° C, when they died immediately. Other experiments included high altitude experiments in pressure chambers, experiments to determine how long human beings could survive in freezing water experiments with poison bullets experiments with contagious diseases and experiments dealing with sterilization of men and women by x rays and other methods. There are many references to these and other experiments in the judgment and to the responsibility of the various Nazi leaders and organizations. There is no doubt that thousands of individuals were the involuntary victims of medical experiments and that a high proportion died. Many more died as a result of medical neglect or improper treatment. Finally, thousands of prisoners were put to death by methods

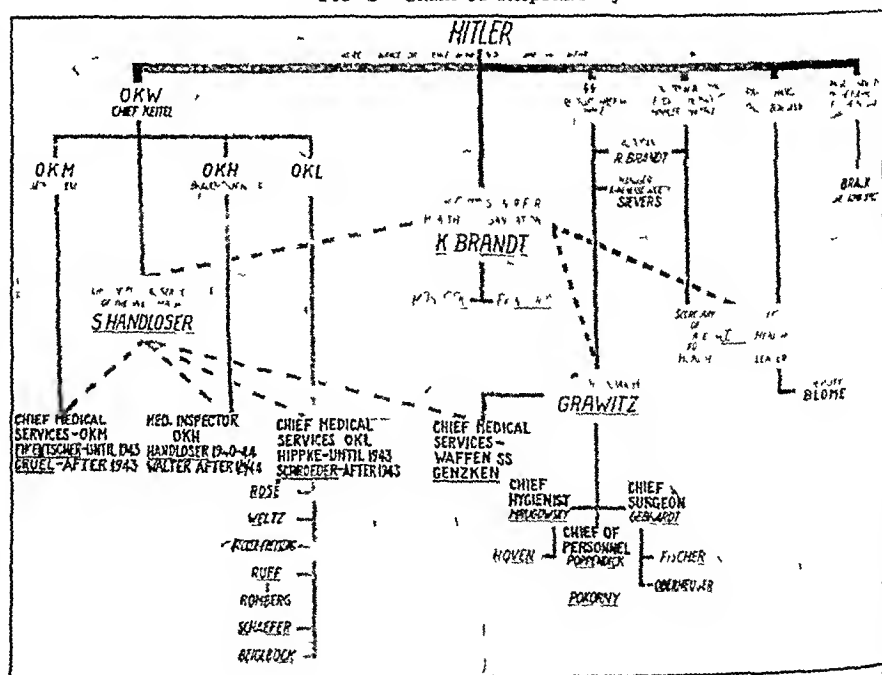

devised and executed by physicians engaged in research into the problem of killing as rapidly and expeditiously as possible.

The Punishment of War Crimes

Before the end of the war the Allies resolved that after victory those members of the Axis Powers who had been guilty of war crimes should be made to pay the penalty and they established an elaborate mechanism to ensure this. In Germany the International Military Tribunal representing Britain, France, Russia, and the United States was set up to try the leaders of Nazi Germany who were deemed to have the major responsibility for the crimes which caused the war and which accompanied hostilities. While this tribunal was still sitting each of the four occupying powers set up its own military tribunals to try the 'lesser fry'. Long before the IMT had reached its decision the other tribunals had completed numerous cases acquitting some defendants, convicting others and sentencing them to death or imprisonment. It is intended that a uniform standard of justice should be maintained by all powers.

Defendants have already been convicted and executed for carrying out medical experiments. Thus at Dachau early in 1946 Dr Klaus Karl Schilling, the eminent malarialogist was hanged for his part in experiments in which some 1200 prisoners were infected with malaria. He had a greater claim than most of the experimenters to the title of scientist. He went to Dachau on the invitation of Himmler to carry out experiments in malaria, on which subject he was a well known authority (he had been a member of the League of Nations Malaria Commission). He was over 70 when these experiments were carried out. Believing that the experiments would provide an unequalled opportunity for the advancement of malarialogy he used a mild strain of benign tertian malaria which would be unlikely to prove fatal in healthy individuals, and he himself appears always to have administered drugs carefully and scientifically. He is said usually to have obtained the consent of the prisoners before he infected them, but at Dachau this could not amount to very much. He was accused at a trial held by the U.S. authorities of having caused many deaths. The Court took the view that 'although Dr Schilling's motive may have been sincere and purely a scientific one, his activities exemplified the Nazi schema which existed at Dachau. The

FIG 2—Chain of Responsibility

investigations. Listening in court one sometimes felt that the prosecution was equally aimed at people who were absent. Thus a, Dr Rascher, who, it appears, was finally shot at Himmler's own order, was concerned with the more revolting experiments on cold and high altitude. The typhus work was carried out by Dr Ding, who committed suicide after his capture. A Prof Hirt, of Strasbourg, who has so far avoided capture, was concerned in the Jewish skeleton collection and the poison-gas experiments.

Fig 2 which is based on a diagram produced by the prosecution shows the relative positions of the various defendants in the Nazi medical hierarchy. To complete the picture various 'absent defendants' are included. The diagram illustrates the curious double pattern of control so characteristic of the regime. The head of every medical department will be seen to be responsible to his own lay chief and also to a medical *fuhrer* who is independent of the administrative head of the department but is himself responsible to some higher authority. The authority of Hitler will be seen to pass down through several channels which divide and then become knit together again in an intricate and all-pervading pattern.

Hitler himself had three main functions—*Reichskanzler*, leader of the Nazi party, and Commander-in-Chief of the *Wehrmacht*. He was therefore the complete dictator, with overall control of every activity in the country. Under him there were the various departmental heads—Keitel over the armed forces, Himmler as *Reichsfuhrer SS* and Minister of the Interior, and others less concerned with this trial.

In German medicine the defendant Karl Brandt occupied the paramount position. At the age of 38 he was appointed *Reichskommissar* for Health and Sanitation, directly responsible to Hitler alone. He had direct and complete control over every medical activity (see Fig 3), and could deal with any department without reference to the administrative head. The defendant Rostock worked directly under him and was responsible for the control of medical research.

The two main branches of the medical services were (a) those of the armed forces under Handloser, responsible to Keitel on the one hand and to Karl Brandt on the other, and (b) the civilian services under Conti (who committed suicide), responsible to the Minister of the Interior and again to the ubiquitous Brandt. In addition the SS, which formed virtually a privileged state of its own, had a separate medical service under Grawitz, another 'absent defendant,' but he again was subject to Karl Brandt's supervision. The navy, army, and air force each had its own medical service, and the chief officer of each was responsible to his own C-in-C as well as to Handloser, who combined his function of chief of the medical services of the *Wehrmacht* with his supervisory capacity over the medical service of the *Waffen SS* (the armed part of the SS which eventually had some thirty divisions in the field).

"Thanatology"

The prosecution has used the word 'thanatology, which they define as "the science of producing death," to describe the experiments. They allege that the object of the majority of the experimenters was not to advance medical science but to produce methods of speedy extermination. This seems to be true of some investigations, in which intravenous injections of phenol and other substances produced death in a few seconds. The work on the effects of poison gas would seem to have been so mixed with the programme of extermination of Jews and others deemed "undesirable" that it is difficult to distinguish experimentation from wholesale killing.

The prosecution has further urged that practically no results of any value were obtained in any of the work. This is a point which needs further study. From what we already know of the typhus work it is clear that a useful evaluation of the various vaccines was obtained, some of these results have already been published.¹ Preliminary studies suggest that the other work may not advance medical science a great deal, for two reasons: first some of the results, particularly those obtained by workers like Rascher, are so inaccurate that they cannot be relied on; secondly, few of the original records are available, because they were destroyed to prevent their capture by the Allies in order to try to conceal the fact that the experiments took place.

Generally speaking there is no doubt that most of the work was badly planned and carried out under conditions where scientific thinking was difficult. The SS was responsible for supplying the human subjects, and Himmler was only interested in quick practical results. This constant political pressure must have had a bad effect. Then the victims of the experiments were not the willing co-operators who have taken part as volunteers in so many experiments in this country, in Australia, and in America. They were prisoners, compelled to take part in work which they knew would quite probably mean their death, and if sabotage was possible they looked upon it as their duty.

The illustrations are reproduced by courtesy of the Public Relations Photo Section Office, Chief of Counsel for War Crimes Nuremberg, Germany, A P O 124-A, U S Army.

ANAESTHETIC APPARATUS

NEW SAFETY CODE

The Medical Defence Union has records of many of the fatal accidents that have followed the administration of anaesthetic gases. Recently the Union arranged a conference of interested parties in an attempt to minimize human errors in the use and assembly of anaesthetic apparatus. Ultimately a committee was set up consisting of representatives of the Medical Defence Union, the Association of Anaesthetists, and the manufacturers of anaesthetic apparatus and gases. This committee has put forward a short-term policy which can be effected immediately and which includes proposals for the distinctive marking of cylinders and pipes, for planned storage, and for the selection and instruction of personnel. Its long-term policy calls for a complete system of non interchangeable connexions for gas apparatus. This will make wrongful coupling impossible, but can be fully achieved only by the introduction and universal use of a new type of cylinder valve, with consequent changes of the apparatus attached to the cylinders. Until such time as this "fool-proofing" can be brought about the risk of a wrong connexion must remain, but a code of practice has now been formulated which should reduce this risk to a minimum.

A British Standard Code of Practice (BS 1319 1946, price 2s net) has been prepared under the authority of the Chemical Engineering Divisional Council in response to the joint representations of the Medical Defence Union and the Association of Anaesthetists. The code relates to gases contained in cylinders for use in anaesthesia, oxygen therapy, and for other medical purposes, to certain features of anaesthetic and gas therapy apparatus, and to gas distribution systems by pipe lines in hospitals. The suggested colour scheme for cylinder identification is as follows.

Table of Identification Colours for Medical Gas Cylinders

Name of Gas	Symbol	Colour of Cylinder Body	Colour of Shoulder, where Different from Body
Carbon dioxide for inhalation	CO ₂	Upper $\frac{1}{2}$ Sea green (BS Colour No 17) Lower $\frac{1}{2}$ Black	—
Carbon dioxide with internal tube (for making snow)	CO ₂	Sea green (BS Colour No 17)	—
Cyclopropane	C ₃ H ₆	Aluminium	Red (BS Colour No 37)
Ethylene	C ₂ H ₄	Mauve	Red (BS Colour No 37)
Helium	He	Brown (BS Colour No 11)	—
Helium and oxygen mixture	He + O ₂	Brown (BS Colour No 11)	White
Nitrous oxide	N ₂ O	Black	—
Oxygen	O ₂	Black	White
Oxygen and carbon dioxide mixture	O ₂ + CO	Black	Sea green (BS Colour No 17) with white neck

The figures in brackets are references to the colours established in British Standard 381—British Standard Colours for Ready mixed Paints.

It is also recommended that no cylinder should be encased in any covering, that the label encircling a gas cylinder should be printed in characteristic colours with the name of the gas.

contained—e.g., in the case of carbon dioxide for inhalation a green label with black lettering—and that the name or the chemical symbol should be stencilled in paint on the shoulder of the cylinder. The same name or chemical symbol should be clearly and indelibly printed on the cylinder valve.

For the visible connecting tubing of anaesthetic apparatus the identification colours should be: oxygen—white, carbon dioxide—sea green, nitrous oxide—black, and cyclopropane—aluminium-coloured tubing with a spiral red line. Pipe-lines where visible should be similarly coloured and in addition, the compressed air-line should be light grey, the vacuum line primrose and the spare line "natural (varnished)".

Finally, the code suggests a type of cylinder storage rack which would differentiate the sizes and colours of cylinders. The shelves are slightly inclined so that cylinders removed for service can always be taken from the one side. The remaining cylinders roll down the incline leaving a space on the other side for the insertion of fresh cylinders.

This code of practice marks an important step forward in co-operation between manufacturers and anaesthetists. Its recommendations should be studied carefully by all who have to do with the handling of gas cylinders. Production difficulties are such that the long-term proposals are not likely to be achieved for some time. Till then, the recommendations of this code, if conscientiously followed, will ensure the reduction to a minimum of the present risks.

RESETTLEMENT OF THE DISABLED PROGRESS REPORT

Up to the late summer the number of disabled persons registered at the local offices of the Ministry of Labour and National Service was 628,000—a surgical group of 289,000, a medical group of 196,000, a psychiatric group of 34,000, and the remainder miscellaneous chiefly eye and ear defects. The resettlement into gainful occupation of a mass of disabled persons equal to the whole population of Lincolnshire calls for long-continued and enterprising planning. About 100,000 of these people are ex-Service of the 1914–18 war, and therefore veterans, some 5,000 are juveniles, and of the remainder about equal numbers are ex-Service of the recent war and non-Service. Women number about 6% of the adult disabled. All these people are eligible for various resettlement and employment schemes, including the scheme whereby every employer of twenty or more workers must take a quota of disabled persons (at present 3% of his labour force), the scheme whereby certain employments are by order designated suitable for disabled persons, the schemes of local authorities, mostly embracing blind persons, and the home workers' schemes under which those whose disablement prevents them from taking advantage of workshop facilities may carry on work at home.

On the recommendation of the Tomlinson Report now four years old, a standing interdepartmental committee was set up in 1943 representing all the Government departments concerned, ten in number, including the Government of Northern Ireland, to watch and assist the development of schemes for rehabilitation and resettlement, and it has just issued a progress report.¹ In England and Wales 333 hospitals, or very nearly two thirds of the larger general and special hospitals, now have active rehabilitation facilities, although in a considerable minority the facilities are only partial—for example, they have remedial exercises but not occupational therapy. In Scotland rehabilitation departments have been developed in the emergency hospitals.

Provisions for Special Cases

Provision for cardiac cases, of which 30,000 have been registered, has been deferred owing to various difficulties, and at the time of compiling the report it had not been possible to set up a special centre. For tuberculosis—pulmonary tuberculosis is given as the disability of 22,000 of those registered

—arrangements have been made for close co-operation between tuberculosis authorities and the local offices of the Ministry in finding employment under suitably adjusted conditions for the individual when he is fit to undertake it. More success seems to have been reached in obtaining part-time employment for tuberculous persons than in providing rehabilitation measures. For the deaf—and 19,000 of the disabled suffer from ear defects short of total deafness—the Government is providing a new electrical aid. Under the new National Health Service there will be provided the necessary treatment of deafness, a scientific assessment of the need for a hearing aid and the aid itself and its servicing. Over 32,000 men and 1,500 women are registered in the psychiatric group and these people will be dealt with by assessment centres—one experimental centre is being set up for England and Wales and another for Scotland—with immediate facilities for employment in the less serious cases and facilities under sheltered conditions for the more serious.

The interdepartmental committee has also surveyed various local or regional schemes. One of these provides special facilities for Scottish miners at the fitness centre in Glencalgies, another is the scheme at the Manchester Ship Canal Docks whereby labourers suffering from minor physical ailments receive medical advice and such reference for treatment as may be necessary. Yet another is the Scottish Supplementary Medical Service, originally confined to the Clyde Basin and to persons up to 25, but now extended to cover the whole of industrial Scotland and persons of all ages. The main object of this scheme is to assist general practitioners in dealing with cases of industrial fatigue by providing consultant and diagnostic services for actual or probable early cases of organic disease. There is no similar organization in England and Wales but it is considered that existing medical services provide largely for proper diagnosis and early treatment. The time is not considered ripe for the institution of a postgraduate diploma in rehabilitation, but special courses for doctors have been held, training facilities for physiotherapists and occupational therapists have been secured, and a hospital almoner service developed. Under the wartime scheme operated by the Ministry of Pensions Limb-fitting Service about 3,900 civilians have been supplied with artificial limbs. The cases of amputation of one arm or one leg in the register of disabled persons number 41,000 of both arms 370, and both legs 1,277.

Vocational Training

About 67 Government training centres are now functioning in which the training of disabled persons is carried out side by side with the training of the able-bodied. This is considered the best arrangement for the disabled. A wide range of manual or quasimanual occupations, all of them requiring some degree of skill is listed, and the course of training is rarely less than six months and sometimes nine or twelve. These courses must now have been completed by about 25,000 disabled persons and a further three thousand have had training for professional, technical, or executive positions.

One important class is the paraplegics, in view of their special limitations and their need for medical supervision. It is stated that the modern methods of treatment and rehabilitation in practice at the Ministry of Pensions Hospital at Stoke Mandeville have shown that the majority of paraplegics are able to undertake remunerative employment under suitable conditions. Further experience is likely to be acquired at two new hospitals which are projected one in the London and the other in the Glasgow area.

The variety of the disablements themselves, of the occupations into which the people can resettle, and of the schemes for enabling them to do so makes it most desirable that some permanent body should be in existence to secure co-ordination and promote the exchange of information. This interdepartmental committee well fills the role, and we hope it will report upon the subject annually or as occasion requires.

Reports of Societies

ANAESTHESIA FOR ABDOMINO PERINEAL OPERATIONS

At a meeting of the Section of Anaesthetics of the Royal Society of Medicine on Jan 3, with Dr STANLEY ROWBOTHAM in the chair, a discussion took place on anaesthesia for abdomino-perineal operations. Dr RONALD JARMAN said that it was now forty years since Mr Ernest Miles had first performed abdomino-perineal excision of the rectum. Notwithstanding the hesitation with which the operation was formerly regarded by many surgeons, it had proved successful thanks not a little, as Mr Miles would acknowledge, to team-work. In considering the operation from the anaesthetist's point of view he laid stress on the careful preliminary examination of the patient. The patient was taken into the hospital at least fourteen days before the operation, during which time he had high colon wash-outs. The anaesthetist could at the same time make his own examinations and estimates. In an experience during the last fourteen years of over 1,000 cases of this kind, the speaker had taken a dislike to ether, and preferred for his own use pentothal and gas-oxygen with premedication by omnopon and scopolamine. The patients were put to sleep in their beds with pentothal, taken to the theatre, given 'light' percaïne, followed by gas and oxygen. Curare could be used with success.

Dr FRANKIS EVANS said that at St Mark's Hospital several hundreds of cases had been treated by means of the synchronous combined excision, which permitted the removal of a rectal growth inoperable by the abdomino-perineal technique. In the light of experience the anaesthesia for these operations became largely standardized and his own preference was for a spinal analgesic in combination with a dilute pentothal intravenous drip to maintain unconsciousness. The patient came to the theatre with an intravenous drip in position. The pentothal administration was started and when the patient was unconscious the spinal puncture was performed. When the blood pressure fell unduly low it was an indication for dosage with adrenalin.

A sample of some sixty cases from St Mark's, twenty treated by the abdomino-perineal and forty by the synchronous combined excision, showed there was very little difference in post-operative complications whether a spinal anaesthetic with gas oxygen or a spinal with pentothal drip was used. The mortality in this series with the abdomino-perineal operation was about 9.8%, and with the synchronous combined 8.1%, but it must be borne in mind that the cases were very bad risks. Curare had been tried in one or two cases, but these had been found to bleed considerably and appeared to be more shocked than patients who had had a spinal anaesthetic.

REHABILITATION FOLLOWING CHEST SURGERY

At a meeting of the Section of Physical Medicine of the Royal Society of Medicine held on Jan 8, Mr HOLMES SELLORS said that the circumstances favouring rehabilitation were better in chest surgery than in general surgery if only because the treatment of chest cases was carried out in institutions where the general tempo of life was more like that of a sanatorium than of a busy city hospital. In chest work the aim was to keep the patients in hospital until they were ready to return practically to a normal life, thus the hospital was likely to be more spacious and of the "green belt" type. The cases were long-term, there were some which stayed only four or five weeks in hospital, but the difficult ones with chronic empyemata and those which developed complications, might be kept in for months, or perhaps up to a year. Some of the investigations such as those for tuberculosis took a long time and during this period a great deal could be done by teaching breathing exercises to prepare for the post-operative course of treatment.

Diet had to be considered, as in the suppurating case the loss of protein over a term of weeks might be quite considerable. The most difficult problem was the psychological one

of the patient in hospital, for as he improved he became restless and later apathetic. The importance of the economic side had been recognized in tuberculosis by the system of allowances, but not to the same extent in chronic chest cases. Occupational therapy was still at its beginning and had not received enough attention.

The medical aspect of rehabilitation resolved itself as a question of chest function. The best example of the long term case was the chronic empyema in which there was usually deposited a mass of fibrin over the pleural surfaces, surrounded by an unyielding contracted chest wall. Secondary scoliotic change, often including wedging of the vertebrae, was the appalling deformity seen too often as a result of mal-treatment of the acute phase of the empyema.

Chest Exercises

The underlying lung worked more or less *pari passu* with the chest wall. It was almost an aphorism that with an actively moving chest wall there was reasonable lung function. The basis of treatment was to get the chest wall moving and to prevent any structural deformity from developing. The type of breathing exercise required was thus based on inspiration and not expiration. These inspiratory exercises were new but physiotherapists who had developed them had demonstrated that they were of inestimable value. The first secret was the teaching of concentration. It was of no use to have breathing exercises for just ten minutes every morning. The patient should be told that of the twenty four hours of the day eight were sufficient for sleep, eight for meals and play and the remainder should be devoted to sedulous training in breathing. He should be taught localized inspiratory exercises, working against some form of resistance which enabled him to concentrate his mind and activity on the area of the chest it was desired to move. The chest might be divided into its various functional parts in relation to movement. In empyema it was generally the basal expansion which was an important movement to regain and such control must be established by the patient. By careful concentration it was possible to move one area and one area only by voluntary effort. The other movements concerned were lateral movements, an attempt to get posterior expansion, and, finally, a ripple almost along the antero-posterior line.

After the general exercises it was very important to see that the stance of the patient and his position in bed were correctly maintained. Subjects had a tendency to avoid discomfort in bed by cramping-in on the bad side of their chests, which actually made them worse and tended to exaggerate all the defects which it was sought to remedy. Unless there were contraindications the patient should be got out of bed as soon as practicable, as by his moving about his general recovery was encouraged. Effective coughing for the clearance of noxious secretions from the lung was desirable, as otherwise the patient was liable to atelectasis and further inflammatory changes.

Occupational Therapy

So far as occupations other than breathing exercises were concerned leather work and toy making had proved their value perhaps more in the case of women, as men were less inclined to take to these simple occupations. These activities must not be allowed to become an obsession though occasionally, as in a great many military cases, they might open out a new permanent occupation for a patient whose disability did not permit his return to his ordinary means of livelihood. In the late stages those attending the patient must avoid any tendency to let the posture become set, as they needed to walk comfortably. It was not easy to achieve a really high degree of functional recovery with satisfactory vital capacity in these patients and it was necessary to make liberal use of the services of the physiotherapist.

At the annual general meeting of the Harveian Society of London held on Jan 15, the following officers were elected for 1947:
 President Macdonald Critchley, MD, FRCP Vice Presidents
 A. Wallis Kendall, MS, FRCS, J. H. Peel, FRCS, John
 Hunter, CBE, MC, FRCS W. Eldon Tucker, FRCS
 Honorary Treasurer Sir Cecil Wakeley, KBE, CB, DSc
 FRCS Honorary Secretaries Peter Turtle, MB Rodney Smith
 MS, FRCS

Correspondence

The Presidents and the Minister

SIR—The letters between the Presidents of the Royal Colleges and the Minister (Jan 11, p 66) get us nowhere. The Act in its present form is anathema to the bulk of us by reason of certain of its provisions which enslave the patient and insult the profession. It was forced through Parliament in this form by Mr Aneurin Bevan. It gives him more absolute authority than any man in peace has had since Cromwell. He can, on the plea of national health, prohibit beards or make cremation compulsory and is answerable to nobody but Parliament. He can dodge that by saying that it is not in the national interest to say why he so acted.

His answer that the salary basis is to help the profession is just soft soap and eyewash. The Lord Chancellor stated emphatically that it was to control medical certification—I am etc.

Newton Ferrers Devon

W F BENSTED SMITH

SIR—It is with misgivings that one reads of conversations between the Presidents of the Royal Colleges and the Minister of Health. An impasse is to be deplored but is not of our making. The one thing above all others upon which the Minister insists is the one thing above all others which makes it fundamentally impossible for the profession to negotiate with him—i.e., his power of dictatorship to issue edicts and make rulings from which there is no right of appeal to the courts of justice.

It is utterly futile to attempt to negotiate with a dictator because any apparent "concessions" he may make can be rescinded at his own sweet will. This determination to bypass the judiciary and render impotent the Common Law of England is apparent not only in the N.H.S. but in all the new laws being passed. In the farmers' sphere our 'Willesden affair' has its even more glaring counterparts in the *Odlum* versus *Stratton* and *Miller* versus *Essex War Agricultural Executive Committee* cases, which provide us with samples of what we may expect under bureaucratic dictatorship. The medical profession is in the forefront of the defence of British freedom against the onslaught of the National Socialist State, and we have a moral duty to the public in general as well as to our patients in particular to stand firm—I am, etc.,

St Germans Cornwall

W H SPOOR

SIR—The letter (Jan 11 p 66) to Mr Bevan in which three distinguished consultants have expressed the hope that negotiations about the Health Act between the doctors and himself will be continued appears to be written without recognition of three vices inherent in the Act. The writers seem to have turned the blind spot of their vision upon them.

The G.P.s have declined to negotiate. One does not negotiate about vices. I wish to refer to one of them. It is the payment by salary. Why does Mr Bevan stipulate this? It is a feature which vitiates the age-old relation of patient and doctor. In Mr Lloyd George's Act he skilfully avoided such a desecration, the panel system preserved the individual freedom of both parties, patient and doctor, but payment by salary destroys the ethic which two thousand four hundred years have built up. The doctor is to be paid by his master, who will be the State not by his patient. *Ipso facto* despite denials, he becomes a state servant. A private doctor, under the Hippocratic tradition owes his duty to the patient alone.

Why does Mr Bevan wish for this change? It was not in the first instance his suggestion but it arose from the Beveridge report. Sir William Beveridge (as he then was) disclaimed interest in the medical services of the scheme except in this, that the doctors must be so paid that in a system affording the large benefits proposed the certification must be safeguarded by the method of their payment. Safeguarded? That is the toad ugly and venomous, which lurks in the leaves of the Beveridge report. Its reappearance in the Act is one of the three vices which render that statute unacceptable to the G.P.s.

Their tradition is that they certify their patients' illnesses upon their conscience and their professional knowledge, uninfluenced by any extrinsic considerations. They see in this salary an unblushing inducement to deviate from their duty which begins and ends with the certification of the truth. No single action of the legislature could more effectively shatter the mutual confidence of doctor and patient. Safeguarding the State's finances is not the doctors' concern. Doubtless consultants will seldom be called on to confront such a problem, as is the G.P. many times a day. That may explain the blind spot in the vision of Mr Bevan's three correspondents—I am etc.,

Holmes Chapel Cheshire

LIONEL JAS PICTON

SIR—The recent unilateral action of the Presidents of the Royal Colleges in approaching the Minister of Health without consulting the profession is to be most seriously deplored. We regret to have to describe their action as autocratic, unrepresentative, and, in effect an abuse of Office.

The Royal Colleges are not democratic bodies. Their constitution is that of autocratic corporate bodies. Nevertheless in a democratic age the Colleges should adopt democratic methods thereby enabling Fellows and Members to voice their opinions through properly elected representatives. Presidents of corporate bodies are not necessarily chosen because they share the majority opinion on medico-political matters but rather for their personal popularity and prestige. In the present crisis between the Government and the medical profession it is not unreasonable to suggest that these three distinguished men are representing themselves and possibly their Councils, consisting of a total of about 100 general practitioners. Moreover this step has apparently been taken without consultation with the B.M.A., which represents 52,000 medical practitioners including a large number of Fellows and Members of the Royal Colleges.

Medical practitioners are naturally astonished that this undemocratic step should have been taken by three responsible men who have duty to the profession and public. Perhaps one may be permitted to ask whether the Presidents have been lured by the politically inspired call for 'statesmanship' by *The Times* (a newspaper which seems to have developed into a Government organ travelling under a Tory label). Should this be the case then we have an impending Medical Munich.

This unprecedented action taken by the Presidents, which is liable to sabotage the results of the plebiscite has filled practitioners with alarm and created a serious lack of confidence in the Royal Colleges in their assumed role as leaders of medical policy.

It is hoped that the B.M.A., as the representative and recognized negotiating body of the profession, will adhere unwaveringly to the clear mandate given by the majority of private medical practitioners—We are etc.,

W C D Muir,	K J L Scott,	N K Stott
W D Henderson,	Stuart Haycs,	J M S Evers,
F J Beilby,	J B Carlin	J W C Symonds
L G Higgins	Isobel Mitchell	Tudor Miles

SIR—The President of the Royal College of Surgeons asks for the forgiveness of the Minister of Health for his intervention. Surely the trespass has been committed not against the Minister but against that special meeting of Fellows gathered in that crowded hall on Nov 29, and to whom he pledged that the Royal College of Surgeons would take no action that was not in accord with the wishes of the main body of the profession. Indeed, he may not have acted contrary to the "word" of this resolution, but it would seem that the intervention is contrary to its "spirit" and to the wishes of that meeting and that majority which has said "No".

Let us hope that this action will not render the result of the plebiscite worthless, as some would wish, and that the B.M.A. Council and those who give the mandate to the Representative Body will have no difficulty in washing away the dust which may have got into their eyes, so that they can see that Mr Bevan is still only prepared to negotiate "within the Act" and will only endeavour to meet any views of the profession which do not conflict with the principles of the Act. It is because of

these differences in principles that the majority of the profession has said "No"

Let us then unite and support to the full the Council of the B.M.A. in the decisive action it took on Dec 11—We are, etc,

London W 1

CYRIL E BEARE
ANTHONY GREEN

The Principles of the Act

SIR—A good deal of interest and curiosity must have been aroused throughout the profession by the publication (Jan 11, p 66) of a letter addressed to the Minister of Health by the Presidents of the three Royal Colleges. However this may be, the Minister's reply does not alter the situation one iota. "If discussions take place, I shall endeavour to meet any views of the profession which do not conflict with the principles of the Act." So says the Minister, discussions are like cobwebs—to catch flies, but the power is in the law, and there's no disputing with it but upon the sword's point.

What are the principles of the Act? The Government is set on nationalization. In order to establish its policy it is bound to bring medical practice under its control. The final arbiter on all matters medical, surgical, gynaecological, or otherwise is to be the Minister of Health. The medical man is no longer to be his own master, on the other hand he is to have a master. Those are the principles of the Act. The spectre of State dictatorship faces us, our freedom is threatened. It falls to our lot, therefore, to oppose with all the energy at our disposal the evil forces which confront us. If the liberty which is ours is seized by those with greater zeal, greater unity of purpose, whether based on ignorance, class prejudice, or mere political ambition, then woe betide us. The character of our profession as a corporate body is on trial. We have said "No." It remains to show that we mean it, whatever the cost. Let it be understood that the struggle we are entering is not confined to the defence of our own liberty but is part of a much wider struggle in defence of the liberty and individualism of the whole British race—I am, etc,

Kilgley, Yorks

H. M. HOLT
Medical Officer of Health

Democratic Choice

SIR—The other evening I listened-in to the broadcast on the 'Vesting Day' for mines. I notice how anxious the powers that be were to emphasize that the miners would be consulted via their democratically elected representatives. I should like to know why the medicos who are expected to work the Health Act are not to be consulted, and their representatives are appointed by the Ministry, not elected.

As regards the "closed shop" I remember that in the early days of trade unionism some employers would not allow their men to join trade unions. This was described as tyrannical and narrowminded. Is not the "closed shop" movement exactly the same thing from the other point of view? Let us be free men and masters in our own home—I am, etc,

Wolverhampton

E. HAYLING COLEMAN

Women Doctors in the Health Service

SIR—Dr Enid A. Hughes, in her letter (Jan 11, p 71), writes that provided her living is secured and her professional integrity assured she is not going to stand upon the question of salary and selling of practices. She voted "No" in the recent plebiscite as an expression of no confidence in the present committee to represent the present generation of doctors.

I would ask her and all medical women who hold her views to consider very seriously what the future of women in medicine is likely to be in a National Health Service under the present Act. We know that a recent committee was set up to go into the question of equal pay for equal work as regards men and women, and we know its findings. Once the shortage of doctors is overcome what guarantee have we that women doctors will not be asked to accept lower fees than men? Then we will be servants of the State and no longer free. *Vestigia nulla retrorsum* (no footprints backward at the lion's den).

It is not to any Government nor to local authorities (a thousand times no) that we owe the recognition of equal status

with men in medicine, but to the British Medical Association, which (once it saw the light) has stood firmly and consistently for equal pay for equal work. And it is to those members of the Association—men and women—over 65 to whom we owe most. They sowed the seeds of the harvest we now reap. Have we the right to scorch the earth for those who come after? I would venture to remind Dr Hughes that she would have had no vote at the recent plebiscite and no future in medicine were it not for these older members of the Association whom she derides—I am, etc,

Marden Kent,

FREDA NEWMAN

National Health Service Act

SIR—It is abundantly clear that the National Health Service Act gives the Minister of Health complete personal power over the whole health service of the nation—that is to say over the hospitals, their management committees, and regional boards, and, most important of all, over the personnel of the Service. What power!

Will the members of the medical profession agree to work in a Service in which they are under the autocratic control of a Minister? They can hardly do so, and if they do they will lose their independence and become subservient creatures. By this deterioration and degradation of their doctors the people will suffer.

The blight of prospective Ministerial control is already affecting the attitude of us doctors. We begin to feel like lambs brought to the slaughter. Some of us are beginning to be afraid to say much lest we should earn a bad mark. The recent letter from the Presidents of the three Royal Colleges addressed to the Minister of Health illustrates this attitude. It deals with details rather than principles, and it ends with the obsequious phrase, "We hope you will forgive us for intervening." And so we doctors are being gently led by our leaders into a completely humiliating position. The Presidents of the Royal Colleges are simply selling the birthright of the medical profession, and the people will suffer.

At the meeting of the Marylebone Division of the B.M.A. held on Jan 14, the following motion, originally resolved by the Council of the B.M.A., was carried by 143 votes to 9.

"That the Negotiating Committee be advised that in view of the results of the plebiscite the Minister be informed that because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the Committee is unable to enter into discussions with the Minister on the Regulations to be made under the Act."

In a subsequent resolution, which was carried with only five dissentients, the meeting expressed willingness to co-operate with the Government and anticipated that this co-operation would require new statutory action by the Government.

This matter of Ministerial control, this "terrific centralization of power in one man" as Lord Horder said when the Bill was debated (second reading) in the House of Lords, is a matter of principle and one on which the whole profession should be asked to vote. It is a simple issue, and it is maintained that the Act must be modified at least in this respect if good doctors are to work in the new Service—I am, etc,

London, W 1

GEOFFREY EVANS

SIR—I believe that Mr Reginald Payne (Jan 18, p 102) has performed great service in writing and you, Sir, in publishing his dispassionate survey of the National Health Service Act against its background of present-day legislation by the State. Those who read this, whether within or without the profession if their integrity be accepted, can have few doubts as to the future.

One must set aside those whose political views render them incapable of unbiased judgment, but there remains that surprisingly large section of the community who indulge either in muddled or wishful thinking or whose power of reasoning is distorted by misapplied sentiment. It would seem well nigh inconceivable that these individuals can blind themselves to the futility of negotiation with the Minister over details within the framework of the Act, which can be only trivial in the light of the grave injustice which has become law. To do so will shift the responsibility for its overwhelming defects squarely upon the shoulders of the profession, and those who allow

3 vitamins

against the winter

VITAMIN B₁ VITAMIN C NICOTINIC ACID

Especially at this time of year, ample nutritional reserves are essential allies to the patient's resistance and recovery. Three important vitamins however—B₁, C and nicotinic acid—are water soluble and therefore cannot be stored against the winter. Combined deficiencies of these factors are frequently responsible for the debility, fatigue and generally run-down states that are particularly prevalent in winter time. Certain angiospastic conditions, notably chilblains, may have the same root cause. Nicorbin Tablets combine these water soluble vitamins in therapeutic amounts providing a convenient and certain means of ensuring an adequate intake. Given thrice daily Nicorbin Tablets exert a powerful tonic influence in deficiency states. As a winter routine Nicorbin Tablets prescribed in conjunction with Adecolin (vitamins A and D) are an aid to all round vitamin nutrition.

NUTRITIONAL MACROCYTIC ANÆMIA

Nutritional macrocytic anaemia is now encountered in non tropical as well as tropical countries. It is associated with malnutrition due to poverty, to unavailability of foodstuffs or to voluntary limitation incurred for religious or other reasons.

According to current theory this type of anaemia is caused by deficiency of vitamins of the B₂ complex as yet unidentified. Marmite contains the essential factors of the B₂ group and its striking value in the treatment of nutritional macrocytic anaemia, including the anaemias of sprue and coeliac disease may be due to the presence of one or more of these components.

VITAMIN C B.D.H.

There is a close but as yet unelucidated connection between vitamin C and protein anabolism in most if not all, of its aspects. The formation, growth and maintenance of all protein structures appear to be dependent upon an adequate amount of the vitamin for normal progress. Generous extra-dietary supplements of vitamin C accelerate convalescence, aid in promoting early and *satisfactory healing of wounds, burns and fractures* and possibly reduce susceptibility to infection by promoting efficient formation of 'antibodies'. Further information is available on request.

themselves to be gulled by the honeyed words of the Minister are doing a disservice both to the profession and the public, and must lay themselves open to the charge of seeking self aggrandizement

The alternatives before us now are clearly defined to uphold freedom of the individual against tyranny or to acquiesce in the serfdom of a totalitarian state. If any other warnings need be sought other than those expressed by Mr Reginald Payne, let the unconvinced seek out his edition of Plato's *Republic* and read what that great philosopher wrote of his time—I am, etc.,

Windsor

CHARLES TAIT

SIR—May I express my admiration for Mr R T Payne's article (Jan 18, p 102) and my gratitude to him for his lucid and factual presentation of his case. It is inconceivable to me how any intelligent person can read this article and have any doubt left as to the essentially authoritarian basis of the National Health Service Act.

Like Mr Payne, I have read with care Dr C K Allen's book, *Law and Orders* and like him I have no pronounced political views, and I am as anxious as anyone to see a democratic health service established. Mr Payne has expressed my own views, and the views of many of my colleagues with whom I have spoken, with a clarity and a felicity of expression which I could never hope to equal. In my ignorance I do not know what high office he holds in the counsels of the profession, but obviously he is a leader we would do well to follow, as he knows his facts, is quite without prejudice, and has the ability to convince the wavering and instruct the uninformed—I am, etc.,

Southport Lancs

R R M PORTER

SIR—There appears to be a great deal of loose thinking in the matter of whether opposition to the Health Act is or should be political. Surely the answer is clear enough. The question is political, nor can it be otherwise, as it deals with objections to a method of government by a political party. The sneer that opponents are actuated by political motives can only be justified if we are voting against our consciences to further political aims. I venture to say that the profession does not in general act in this manner.

May I refer for a moment to my own attitude as an illustration, I think, of an average reaction. I hold that a sincere political belief is largely ethical—i.e., it must be in support of the party which is most likely to carry out what we believe to be best for the people of our country. I am cynic enough to believe that most MPs of all parties are not living up to their expressed utterances or even in fact to the ordinary standards which we expect of those whom we meet in everyday life and would make our personal friends. So I vote for the party which I consider more likely to carry out my own personal wishes in legislation, and that usually happens to be the Conservative Party. I was not in the least pleased with Mr Churchill's action in launching a Health Service Bill while the war was still on and the profession far too busy with war work to give any time to serious consideration of the shaping of such a Bill, and I doubt whether we could have been sure of getting our minimum requirements for our patients and for ourselves from the Coalition Government, but we were at least invited to discuss and negotiate in the preliminary stages. The Labour Government has refused to consult us before the passing of the Act so we are fighting a political battle willy-nilly, and fighting it as anti-Socialists in this respect.

When I read the last paragraph of Dr Cardew's letter in your issue of Jan 4 (p 29) I realized that we are even in your columns being treated to the typical oratory of the soap box. The unctuous assumption that he possesses all the virtues and that we, poor inhuman wretches, have been grinding the faces of the poor for years is just such typical nonsense and might so easily have emanated from Transport House. Surely Dr Cardew has something more intelligent to say than this. Perhaps he will come down to brass tacks and tell us frankly what he thinks of Willesden and of the "absent treatment" by medical men in the Ministries of Dr Foxell's Birmingham patients. These are the vital things we are up against and must settle before it is too late. After all, quite a proportion of our profession still does put the patient first and resents only Socialist advice on how to be kind to humanity.

So may we not clear the air a bit by acknowledging frankly that this is a political struggle and that we are rather hypocritical when we emphasize that the other man is holding honourable and sincere views etc., etc. It sounds nice and broad minded, but we just don't think it's honourable to deprive a dying person of what is necessary for his comfort and existence at the behest of stupid people in Whitehall. We don't think it's just a naughty, mischievous action to try to discharge the staff of a hospital (desperately badly needed) to please the trade unionists who are running this Government and we are fighting the Act because we see, if we have any intelligence, that these things are just those that can occur much more easily under the Act and undoubtedly will—I am, etc.,

Maidenhead Berks

A DANGERFIELD

SIR—I have just seen the pamphlet issued by the British Medical Association entitled *Your Doctor or the State's Doctor Which Do You Want?* As an ex-member of the Indian Medical Service I wish to protest at the travesty of the facts contained in the pamphlet regarding medical officers of the Forces and the medical treatment of Service cases. The first duty of Service medical officers is to prevent disease, and secondly to provide treatment for sick and wounded. The object of the latter is to return their patients to duty as soon as possible compatible with the interests of the patient. They are definitely responsible for and also to the patient. They certainly are responsible to their superior officer in the same way that a house-surgeon or registrar is responsible to his chief.

Regarding promotion and pay increases length of service is the main factor where the medical officer is in every way suitable but annual confidential reports are the main basis on which accelerated promotion and specialist appointments are made. These confidential reports must be seen and initialled by the officer reported on immediately after initiation and again when higher authority has made any remarks. The medical officer has the right to query any remarks on his report which he may consider adverse.

I take particular exception to the remark in the pamphlet "but for minor complaints and worries the prescription of a No 9 pill and the command Dismiss!" This is a libel on Service doctors as it would be on private practitioners from whom Service doctors are drawn. I wonder if the writer of these remarks dates back to the South African war, when, I understand, there was a ditty sung to the tune of "Clementine" as follows: "Every ailment from a velvet sore to a dislocated spine can be cured, in a moment, by a dose of No 9." I also consider the remarks, "The task of the Forces doctor is to make all ranks fit for duty and to protect the Pensions Fund" as most unjust. The medical officer's duty is to keep all ranks fit as far as possible and, in questions involving pensions to give his true opinion, based on medical grounds—I am, etc.

Newmarket Suffolk

W L WATSON,
Colonel I.M.S. (retired)

SIR—Modern methods of propaganda especially when they are used in conjunction with what Douglas Reid calls "infiltration" [sic] can accomplish almost anything. The rape of Czechoslovakia, which was Munich, was greeted with widespread rejoicings in the House of Commons: there were few dissentient voices. It was not until Hitler had completed the dirty work that public opinion was profoundly shocked.

History repeats itself. Our profession has been divided and inexorably lured to the very brink of the Gadarene slopes, and now the final softening-up process is in full swing. There is a glut in red herrings, and many of those who voted No and intended to stand firm are being swept off their feet as yet another minority attempts to impose its will. The recent action of the Presidents of the Royal Colleges is hailed by the *Yorkshire Post* as "statesmanlike" (though other names have been given to it), *The Times* nods her venerable head in approval and even the *Daily Mail* says that "the doctors will make a great mistake if they do not accept the Minister's invitation to

negotiate concerning their objections *within the framework of the Act*

If our objections could have been met within the framework of the Act, why the plebiscite? Surely those of us who voted 'No' did so because we believed that the Act itself required amendment in certain vital aspects. That situation has not changed at all though there seems to be a conspiracy to make everyone believe that it has. The future well-being of our profession and of those we serve is at stake, it lies most assuredly in our own hands if we will but stand by our principles—I am, etc.,

Hessel E Yorks

R HFRMON

National Service for Health

SIR,—Dr H B O Cardew (Jan 4, p 29) refers to the Labour Party publication called *National Service for Health* and states that the Act in no way conflicts with this announced statement of policy. This is a matter of opinion, since different people anticipate the results of the Act in different ways.

There can be no doubt, however, that in one important respect the statement of policy in that publication is directly at variance with a statement made on behalf of the Government in the House of Lords during the debate on the Bill. The booklet states on p 18. In the Labour Party's opinion, therefore, it is necessary that the medical profession should be organized as a national, full time, salaried, pensionable Service. In the House of Lords the Earl of Listowel the Postmaster-General used these words. It was not and never had been the policy of the Government to institute a full time, salaried medical service, or indeed to do anything else that would wreck the whole health scheme from the outset. Perhaps Dr Cardew would like to try and explain these diametrically opposed statements, which he has apparently preferred to overlook—I am, etc.,

Hungerford Berks

D H STUART BOYD

The Act and Freedom

SIR,—We have, thank God, won the first battle for freedom but many of our profession still seem to think that the new 'Health Act' is a measure about health. This is a fundamental mistake. The title is entirely misleading. The real object of the Act is complete political and economic power over the profession, hospitals, and patients. It is a major part of a vast scheme for planned control of the nation and of every individual in it. Already our liberty is immensely curtailed compared to what we had ten years ago and month by month our freedom in all directions is being diminished.

We the medical profession, are now the strongest and biggest obstacle to State domination and State control. We must stand firm. We must insist on every one of the objectionable clauses in the Act being dropped completely before we will work under the Act or insist on a new Act without any such clauses being brought forward.

The B M A has done well but only at the last. Much more publicity and information should be given at public meetings in the towns and in the Press. 'Only be strong and very courageous.' We must act with persevering courage and confidence. We have the power, and if we use it now to throw out this infamous and un-English Act we shall have struck a major blow for freedom. We shall have begun to win back liberty not only for ourselves but for every man woman, and child in England—I am, etc.

Winchester

SYBIL TREMELLEN

Medicine and the Ministry of Food

SIR,—As a pathologist I was very interested to read in the *Journal* of Jan 11 (p 69) that the advisers of the Ministry of Food had furnished Dr H Foxell with the following information. Our advisers are of the opinion on the pernicious anaemia is completely controllable by modern therapy. It would seem therefore in view of this information that I have discovered a new disease rare enough I agree, which consists of a macrocytic anaemia associated with gastro intestinal disturbance subacute combined degeneration of the spinal cord, and the bone marrow of an Addisonian type of pernicious anaemia, which gives little or no response to liver or any other form of modern therapy.

During the past few weeks I have spent some time reading the current English, American, and Russian literature dealing with the relationship between protein deficiency, in particular deficiency in amino acids, and macrocytic anaemias in general. Perhaps I have been wasting my time and should await further bulletins from the Ministry of Food—I am, etc.,

Southport Lancs

JOHN H HANNAN

The Plebiscite

SIR,—At a meeting of the West Sussex Division of the B M A on Jan 12, I was amazed at the confusion, which exists among doctors about the plebiscite. Many, like myself, had voted 'Yes' and were not at all clear whether this implied approval of the Act as it stands or approval of negotiation. To my mind the plebiscite has tended rather to confuse the issue and has divided the profession into three, and not two, groups: (a) those in favour of the Act as it stands, (b) those against the Act as it stands, but in favour of negotiation, (c) those against the Act and against negotiation on it. There is no means of telling what proportion of those voting 'Yes' fall into group (b), and my impression from this meeting was that this proportion was high. It is important for the Minister and the profession to know this proportion as it will profoundly influence what action each should take.

The Minister and the profession are each endeavouring to create a comprehensive medical service which will be in the best interests of the public. It does seem a great pity that all negotiation between them should cease. What the profession has expressed is not a refusal to negotiate but a refusal to negotiate on the Minister's closed terms—the Act as it stands. In his latest letter Mr Bevan has adopted a more conciliatory tone, but can still only negotiate within the terms of the Act. The percentages in the plebiscite show that it is the general practitioners who need to be conciliated. May I suggest to the Minister that the most thorny point remaining would appear to be the goodwill of their practices. If the Minister is sincere about the points he has raised in his letter, including appeal from the decision of the tribunal, then it should be possible to reach a compromise—I am, etc.,

Chichester Sussex

JOHN D WHITESIDE

SIR,—The voting in the recent plebiscite indicates that the majority of doctors under 40 are in favour of negotiations, while a majority of those over 40 are against. It would be interesting to know what proportion of delegates at the forthcoming Special Representative Meeting belong to each of those age groups. The discrepancy between the result of this vote with its narrow majority in favour of suspending negotiations and the overwhelming majority vote against the main principles of the Act at the last Representative Meeting needs some explaining. I believe that the older age group is in a large majority at those local meetings where the representatives are elected. I cannot think of any other explanation.

Recent experience has shown that to get us anywhere we need a 90% backing of our members. We have not got this backing in this matter, and I believe that this small majority vote does not warrant the suggested action of Council, which will only succeed in splitting the profession and will get us nowhere—I am, etc.,

Nelson Lancs

T D CULBERT

SIR,—Most of my medical service has been performed abroad where I have learnt to appreciate virtues other than British, but such racial pride as I possess is founded on my kinship with the millions of sturdy men and women who have made us what we are, with the 'village Hampdens' as well as with the Cranmers and Cromwells, Miltons and Bunyans, Wesleys and Wilberforces of British history. Can we not then consider the subject of the plebiscite purely from its ethical aspect? Is this Act such as our fathers would have laid down their lives for? Surely it hasn't come to this that we must ask how others will vote or act before we decide to stand by or reject principles? What has the crowd to do with our conscience?

Let us have unity by all means if we can win men to our self and serve only the best. Men may accuse us as like, but as many of us see it we face a crisis in our nation.

life If freedom to treat the sick in the time-honoured personal way, regardless of time and strength and cost, is to be sacrificed to soulless regimentation, then a big step will have been taken away from the freedom of the personality for which thousands have suffered and died A national Service, yes! Equality of treatment, yes! But not at the price of becoming robots

There seem to be three main streams of thought represented in the correspondence, the political, the selfish and the altruistic Can we not all seek to join the last, or at least keep the plane of discussion above selfish or party levels?—I am etc,

Liverpool

FRED R CRADDOCK

A Realist Considers the Plebiscite

SIR—Whatever the plebiscite may or may not have done it has at least shown that most of us are in medicine to get the best living we can out of it The majority of the consultants vote "Yes" because they see private practice remaining *in statu quo* and a chance of getting paid in the future for doing what they do now for nothing Those employed in public health work and municipal hospitals vote "Yes" because they don't see how they can be any worse off, and they might possibly gain something The G.P., seeing before him the swings of decreased income and control increased to potential tyranny—but no compensatory roundabouts—votes No Then he shrugs his shoulders, grabs his bag, and trots off to his branch surgery

Now that the pietistic twaddle recently so freely spewed about the Press has been debunked, let the Minister realize that we are a body of craftsmen ready and anxious to do a decent job for decent pay and decent conditions of service Let him now put forth some definite and positive offer in respect of (a) remuneration, (b) compensation, (c) working hours, instead of the hideous blackmail of "If you don't sign on the dotted line on the proper day you get nothing" Failing this let him huff and puff and threaten to blow our house down as much as he likes, while we will continue our work as in the past, fortified by the knowledge that no service can be implemented without the co-operation of the poor G.P.—I am, etc,

West Wickham Kent

F M SANDFORD

Amending the Act

SIR—Acts are made by Parliament, but the regulations are made by the Ministers concerned To alter an Act needs the assent of Parliament, whereas the Minister can alter his regulations at will The three Presidents in their letter to Mr Bevan (Jan 11, p 66) state that "the implications of some of the proposals for the new Service are not clear to the profession" The specialists may be confused but the majority of G.P.s are not, although both need very definite reassurance from the Minister Mr Bevan's answer is crystallized in one sentence of his reply "I shall endeavour to meet any views of the profession which do not conflict with the principles of the Act" Put clearly this means that he is eager to negotiate about the regulations—i.e., the details, furnishing, and trappings of the measure—but is not prepared to take any steps whatever to remove the bars and padlocks on the structure of the Act which make it a potential prison for the freedom of patient and doctor alike

If the B.M.A. therefore decides that it would be futile to enter into discussions on regulations and details while the majority of doctors are opposed to the very structure of the Act then the Association has three courses open to it (one of negative inertia and two of positive action)

(1) Let the Council of the Association state (a) whether it proposes to let matters slide in the belief that the ballot results indicate that the profession will not work the Act or (b) whether it realizes that matters have gone too far (particularly with regard to hospitals) to regain the *status quo*

(2) In the latter event the Council should take action by obtaining the detailed opinion of the profession on the seven principles at stake then in consultation with the best legal advice work out such amendments to the structure of the Act as would enable the profession as a majority to co-operate wholeheartedly in working such an amended Act

(3) Having mapped out such amendments as are essential to satisfy the majority of the profession both from the doctors and the patients viewpoint, the Council should then employ the ablest journalists and publicists to put the profession's view before the public and thus pave the way for an amending Act

It would be far better to make a voluntary levy of 10s per member in the immediate future to provide some £20 000 for a fighting fund to finance the above projects and ensure a successful Health Act, rather than wait for the enforcement of the present Act as it stands and then make a levy of £25 per member for a 'failure fund' to assist those who will be hard hit if they stay outside a bad service on questions of principle—I am etc,

Dorchester Norfolk

E IVIMY PUDDY

Disunity in the Profession

SIR—The medical profession is at present wasting a great deal of breath, temper, and time in discussing whether or not it should negotiate with the Minister of Health Anyone who is familiar with the present trend of opinion among Service doctors and—more important—students knows that, as with the Lloyd George scheme of 1911, the Government, determined to bring in the system, will find or create doctors who will work it, no matter if the B.M.A. negotiates, refuses to negotiate, or stands on its head The medical profession is—let us face it—woefully disunited, and this disunity is at the root of our troubles, for while other groups of working men have been for the past few decades, steadily improving their pay and conditions by corporate action and collective bargaining the medical profession has secured scarcely any improvement at all Indeed, having regard to the increased taxation and cost of living one may say our material prosperity has probably declined

If the doctors were to unite in a single, universal trade union (based at any rate upon the B.M.A.), they could enormously improve their pay and conditions within a few years Think of it six weeks' holiday with pay every year, a 40 hour week, a secretary for every practitioner, retirement with pension at 55 or 60 We might even force local authorities to pay nurses almost as much as shorthand typists There would be no need to worry about public sympathy with our demands, any more than the lorry drivers or coal miners do

One realizes of course that the present generation of doctors are not likely to act together in this way Many would altogether object to the principles involved some are too shortsighted, some are too lazy But it does seem that doctors of the future may smile as they look back upon this present pointless struggle—I am, etc

Crowthorne Berks

GERALD O GORMAN

Foretaste of Control?

SIR—I beg space to make comment on Dr Wilfred Harris's letter (Jan 11, p 69) on the subject of the Ministry of Food's reply to Dr Foxell's request for extra fat for his now posthumously famous patient Dr Harris would seem to maintain that whereas in this case the Ministry was fatuous in its reasons for refusal, he would regard it as more sane if a panel of experts, advising about a patient they had never seen, refused what was required to maintain life on the grounds that life would in any case terminate shortly, even with the extra nutrient recommended by the attending physician I do not know how Dr Harris would reconcile this sentiment with the spirit of the Hippocratic Oath or with even the most attenuated forms of humanitarian morality but I trust that the number of the profession who would be willing to withhold prescription from patients whom they had never seen, but whose poor prognosis they had gleaned from another's letter, would be few I, personally, would prefer any amount of Ministerial muddle, misunderstanding and delay to this

As to the waste of six persons' butter ration perhaps I am insane enough to believe that even in this utilitarian age which begets sentiments akin to those of Dr Harris the average Englishman would willingly forgo one eight-millionth part of his weekly allocation if this went to ameliorate the condition of a sick fellow—I am, etc,

Orpington Kent

BRIAN D JOHNSON

Health Centres

SIR—I have recently read with great interest an account in the lay Press of a scheme at Dartford, Kent, whereby four practices, involving eight doctors, have been merged into one. Three main surgeries have been provided, and the arrangement enables each doctor to have one day off per week, together with alternate Saturdays, night duty being by rota. Some time ago I put forward a plea in these columns for the early establishment of health centres and regular working hours under the proposed State Medical Service, so I am naturally pleased to see that some others at least share my views. It would be very interesting to have the views of other medical men on this project, and it is to be hoped that the Dartford doctors will be good enough to inform the profession as a whole of the success or otherwise of their scheme in due course.

After eight years of general practice in various parts of the country I must confess myself unable to understand or appreciate the "freedom" which we are supposed to enjoy at present and which so many doctors, writing each week in this *Journal* are so afraid of losing. Most of us already take N.H.I. patients, whom we are bound to attend at all times, and are in addition the virtual slaves of the rest of the community. In theory one can accept only the patients one desires, in practice, as everyone knows, one must take all and sundry. This being the case, I cannot believe that it is fear of "control" which is the true reason for the widespread opposition to any form of State service, nor can one assume that the reason is financial, since the overhead cost of running a practice nowadays is so great that the profits are, in general, extremely modest.

It is unfortunate that in the past we have represented ourselves to the public—falsely, I think—as a race of supermen to whom leisure and a certain amount of private life meant nothing, and that we have allowed them to persist in the mistaken belief that a patient must always have the same doctor, whatever the circumstances. No one can doubt that a proper system of health insurance will be of inestimable value to the community, but it is also clear to every general practitioner that under such a scheme the amount of work will be enormously increased. It is not too much to say that the medical man already has one of the most harassing jobs in the world. Under a State service, unless some suitable provision is made, we know instinctively that our lives will be quite intolerable.

I do not wish to appear dogmatic, but it does seem to me that this is one of the main reasons for the existing distrust and apprehension. I have yet to meet a colleague who believes that the present quixotic system is right or necessary, yet how seldom does one hear the fact mentioned in public. Possibly this is due to fear of the fatuous retort (usually made by some person with ample leisure) "Why did you become a doctor?"

With regard to the direction of doctors, which will obviously be necessary in some form to ensure a proper distribution, I think it is clear that with fixed hours, and the removal of surgery premises to a health centre, this innovation would lose most of its distasteful character, as it would enable the doctor to live where he pleased within reasonable distance of the centre. In conclusion, I would like to express my admiration for the pioneer action of the Dartford doctors and to express my hope that their project will be a success. So far from opposing the new Health Service, it appears to me that the time has come for us to confess our limitations and to request the Minister of Health to provide us with conditions which will no longer be a grave menace to our health and happiness and a constant source of anxiety to our dependants—I am, etc.

Llandudno Junction, Caernarvonshire

H. DAKIN

Supply and Demand

SIR—It seems to be a matter of general agreement that the successful working of a National Health Service (in whatever form it finally emerges) will require an increased number of doctors. The formation of Regional Appointment Boards, therefore, leads to some interesting speculations. One early result might be that Scottish, Welsh and Northern Ireland graduates would be prevented from leaving their own countries which presumably would have first claim on their services if required. If in addition the Government of Eire were to ban the export of doctors the question would then arise of whether

the population of England could receive adequate medical attention.

Further, consideration of their own needs by Provincial Boards might lead to a situation in which graduates qualifying in the provincial universities, would be tied to their own districts and, under a rigid appointments system, doctors from the Dominions might find it difficult to enter English medicine by "free lancing" in resident posts at the various special hospitals in London. What would be the ultimate fate of English medicine and surgery without these convergent and enriching streams? Perhaps, after all, there is still something to be said for the much abused *laissez-faire* and its often forgotten concomitant *laissez-passer*—I am, etc.,

Bournemouth, Hants

T. R. AINSLEY

Soluble Sulphonamide Compounds

SIR—The soluble sodium salts of sulphapyridine, sulphathiazole, sulphadiazine, etc., introduced first in 1939, have been exceedingly useful preparations for intravenous injection especially in the unconscious patient. Their great disadvantage, as is now well known, is their high alkalinity and consequent liability to cause irritation and even necrosis in the tissues unless they are highly diluted. This property is occasionally dangerous—as when, by some inadvertence, these preparations are injected undiluted into the theca, the brachial artery (in mistake for a vein), or the subcutaneous tissue (in mistake for a muscle). From these respective causes I have seen permanent sciatic palsy, loss of an arm, and deep sloughing ulcers of subcutaneous tissue and skin. It would seem therefore that these preparations would by general agreement be superseded as soon as a neutral preparation, proved to be harmless and equally efficient, could be obtained. This I consider has been done.

My colleagues and I have injected the preparation known as "soluthiazole" intravenously or intramuscularly whenever a sulphonamide injection was indicated in this hospital for over two years. We are quite satisfied that this preparation is harmless intravenously, intramuscularly, and even when injected as sometimes happens, deeply into the subcutaneous tissue. The pH value is around 7. The solution is not, however, isotonic. It is hypertonic. Accordingly we have not used it, nor, indeed have had occasion to use it, in contact with mucous or serous membranes. The first preparation which we tried had a tendency to crystallize out in some of the ampoules, but I understand that the preparation now in use has been slightly modified to obviate this defect, and we have seen no trace of crystallization in any of our ampoules for more than a year. The ampoules of 5 ml each containing 1 g of sulphathiazole should be kept at room temperature, not in the cold.

During the course of my teaching of students and post graduates I have been struck by the almost universal ignorance that the problem of the production of a soluble neutral preparation of sulphonamide in concentrated form and completely satisfactory for intravenous and intramuscular injection has been solved. Hence this letter—I am, etc.,

London SE 13

H. STANLEY BANKS

Lung Puncture and Artificial Pneumothorax

SIR—The annotation headed "Pleural Gas Analysis" (Jan 4 p. 21) makes reference to induction of artificial pneumothorax and raises the interesting question of the frequency of lung puncture during this operation. During the induction of well over one hundred artificial pneumothoraces during the last year I have had two cases of *tension* pneumothorax, which followed the inductions within a few hours. In these cases emphysematous bullae were found on the lung surface at subsequent thoracoscopy, and probably the development of the tension element in these cases was due to puncturing these bullae.

That a leak of air at the lung surface does, however, much more frequently occur when it is punctured than these two cases suggest I have no doubt, because I have often been struck by the greater degree of collapse of the lung seen when screening the patient after induction than could be accounted for by the amount of air introduced. Since the great majority of artificial pneumothoraces very soon "stabilize" themselves without any tension element developing, some mechanism must be at work to close this puncture hole. I think it can

simply be accounted for by the relaxation of the previously stretched lung surface afforded by its collapse, which allows the edges to appose sufficiently to close the gap even during inspiration. A simile would be the pin prick in a piece of stretched sheet rubber that closes when the tension is released. In the case of the punctured emphysematous bulla, on the other hand, elastic tissue is reduced in its wall and the lung relaxation will not assist the closure of the puncture to the same degree. Especially will this be the case on inspiration, when the lung surface will be more stretched than on expiration even when partially collapsed. Thus a "ball valve" mechanism is not difficult to visualize where air is admitted to the pneumothorax space during inspiration but cannot escape during expiration, producing an ever-increasing air pressure within the pleural space.

The opportunities for puncturing the lung at induction are great, and I think the incidence is high. Most tuberculosis workers must have been struck by the number of times the lung has obviously been punctured with no attendant ill effects. However carefully the induction is done, air may be withdrawn into the novocain syringe when making sure the needle is not in a vessel, or lung pressures may be obtained on the manometer with the induction needle itself penetrating the lung. I would suggest, therefore, that in the great majority of cases it does not matter if the lung is pierced as the mechanism described above protects the patient from ill effects. Although my series is very small and no definite conclusions can be drawn from it, it is, I think, significant that emphysematous bullae were discovered in the two cases developing a tension element. Although the lung was pierced in many other cases (as proved at induction or later by screening) no bullae were discovered on the lung surfaces at subsequent thoracoscopy—I am, etc.,

London NW 10

PETER STRADLING

Epidemic Gastro-enteritis

SIR—I take the liberty of encroaching upon your space to make a few remarks about the recent outbreaks of "enteritis" which are occurring in maternity units throughout the country. We have had sporadic cases since August, 1944, though no case was fatal and all responded to treatment. It is mostly the nursing mothers who become affected, and it is also noticeable that the nursing staff, especially new pupil midwives, are susceptible.

The onset in mothers is sudden. The patient may be quite well in the morning and yet some hours later may complain of a feeling of nausea. This is seldom followed by vomiting (though occasionally, yes), but appetite is lost and the sight of food aggravates the nauseous feeling. This is followed shortly by a feeling of abdominal discomfort, which in turn is followed by abdominal pain of a colicky nature (umbilical region). Examination of the abdomen at this time shows a certain amount of meteorism to be present and also a "splashing" sensation in the caecal area. Watery stools are passed and may number anything from three to eight daily.

Patients who exhibit these symptoms are generally in the third to the eighth day of the puerperium. The condition clears up in about four days, and its cessation is abrupt.

For those who may be interested I give the routine treatment. At the onset of symptoms nothing in the way of diet is given except milk and soda-water for 24 hours or 48 hours. At the same time two tablets (1 gramme) of sulphasuxidine is given every four hours for 48 hours. If pain is prominent and the stools very frequent tincture of opium 15 min (0.9 ml) is given t.i.d. This generally leads to cessation of all symptoms in 36-72 hours. Occasionally treatment is preceded by the administration of ol ricini 2 dr (7 ml) on the assumption of a toxin being present in the gastro-intestinal tract.

Bacteriological examination of faeces has been abandoned—all findings having been negative. Analysis of the water supply (to exclude metallic poisoning) was done, and a rough examination of the kitchen utensils failed to show any possibility of solvency of metals. We are ignorant of the cause but are inclined to think that food—especially frozen meat—may be involved.

In regard to the newborn babies we have been fortunate (so far) isolated cases have and do occur. Breast fed babies are not immune and indeed a relation can readily be established between infected nursing mothers and their babies. Our worst case was one of a breast fed infant. My own opinion is that while the mother is incubating or developing the toxin a minimal amount may escape through the milk to the infant, and while the amount is not

sufficient to cause symptoms as yet in the mother, it is sufficient to cause disturbance in the baby. A careful watch is kept in the nurseries, and as soon as an infant develops an "unusual" relaxation of stools the following treatment is adopted.

No milk of any description is given. Ol ricini 15 min (0.9 ml) is administered and 0.5% saline with glucose is given by mouth sufficient being given to satisfy basic fluid requirements—that is to say, 2½ oz (71 ml) per lb body weight in 24 hours. At the same time sulphasuxidine 0.25 g is given 6-hourly for a minimum of 36 hours. When symptoms abate half-strength boiled breast milk is given (which is sometimes acidified by adding 2-3 min (0.12-0.18 ml) of B.P. HCl dil). The feeds are increased daily.

It would be interesting to hear the treatment from other units—I am, etc.,

Burnley, Lancs

ANTHONY EUSTACE.

Aspiration of Acute Pleural Effusions

SIR,—Experience in consulting practice and in hospitals, civil and military, suggests that there is not a little uncertainty as to the indications for aspirating an acute pleural effusion. It may be due to the natural desire to prove an effusion diagnosed on clinical signs, coupled with faulty teaching of the inexperienced. Removal of a sample for demonstration to students and for pathological examination is legitimate in a teaching hospital. Aspiration is quite another matter and may be detrimental to the patient. Liaison between clinical teachers should enable every student to see aspiration of the pleural cavity (for this or for some other condition) at least once in his career, and most house-men to perform it. The indications should be clearly taught. I believe them to be as follows.

- (1) Dyspnoea at rest, particularly if increasing.
- (2) Circulatory embarrassment from mediastinal displacement, particularly if increasing.
- (3) Any suspicion of pus—for example, unduly toxic appearance, coated tongue, rapid loss of weight, swinging temperature. It should be noted here that the temperature may be very high with clear effusions, but that it seldom varies by more than two degrees in the day.
- (4) An effusion which shows no sign of absorption at the end of three weeks, particularly if fever is not diminishing. Removal of part will often lead to absorption of the remainder, or examination of the liquid may raise the question of tuberculous empyema or of neoplasm.
- (5) An underlying pulmonary condition requiring artificial pneumothorax treatment. Then it is important to air-replace the effusion before pleural adhesions develop.

I have seen a rise of temperature and increase of effusion so frequently after needling the chest in the acute stage that I prefer not to withdraw even a sample unless one of the above conditions exists, or unless there are strong reasons to suppose that the pleurisy is due to something other than tuberculosis—I am, etc.,

St Leonards-on-Sea, Sussex

E. A. WOOD

Intra-articular Injection in Osteoarthritis

SIR—Over the last eight years at the Charterhouse Rheumatism Clinic and in their private practice members of the staff have treated several thousand cases of arthritis by Grant Waugh's method of intra-articular injection.¹ Some hundreds of these were for disease of the hip-joint. I entirely agree with Dr Vernon Heitnerington's warning (Dec 28, 1946, p 1007) that for these a prolonged treatment is necessary, and also with his remarks on Dr Mawson's paper (Nov 9, p 691) which is certainly too optimistic.

The object of this letter is to draw the attention of your readers to the advantage of using acid potassium phosphate (APP) and acid magnesium phosphate (AMP) rather than lactic acid for the larger joints, as the effect of the injection is more prolonged, consequently the treatment which is by no means painless, need not be administered so often. I make no claim that the salts are more effective than the acid as we have made no comparative tests, but merely that the effect is more prolonged.

In practice for a hip-joint 20 ml of APP is used on the first occasion as AMP is sometimes followed by considerable local reaction. A fortnight to three weeks later 10 ml of AMP is injected, and thereafter the interval is judged by the tendency to relapse, which may be from a month to six weeks. Usually six or eight injections are sufficient.

Personally I now always use the anterior approach to the joint. In about 10% of cases some fluid is present, which should first be aspirated before the injection is made. As much as 35 ml may be withdrawn. For the smaller joints A.M.P. should not be employed, but it is excellent for knees and shoulders—I am, etc.,

Chemotherapy in Virus Diseases

SIR,—May I, greatly daring, be allowed to question the accuracy of a statement in the leading article on "The Chemotherapy of Tuberculosis" (Dec 7, 1946, p 862)? You say "There is so far scarcely a hint that viruses are susceptible to any such [chemotherapeutic] attack, and nothing that we know of their properties and behaviour encourages belief to the contrary." Viruses are large protein bodies, and while little is known as to how they get into a living cell it seems probable that they do not ordinarily multiply except in the intercellular phase. Human beings after attack seem able to develop some method of sterilizing the viruses and acquiring an immunity which is usually permanent—e.g., measles and smallpox—though sometimes—e.g., influenza and the common cold—this immunity is lamentably transient, which suggests that there may be at least two methods of inactivating a virus. There is however a third possible way of attacking the problem besides those of actually killing the virus or in some way inactivating it. If, when once a virus has gained access to a cell, it could be imprisoned within that cell or (more hopefully) other cells have their walls made impermeable to the virus, either the virus would die out or the body have time to develop its defensive mechanism—that is, unless the original dose were already fatal. Is there any possibility that such a thing can be done by chemotherapy or any other means?

Our present knowledge about living cell membranes has recently been conveniently summarized by Jevson and Danielli in their book *The Permeability of Natural Membranes*, and I have good grounds for believing that what follows is at least agreeable to such knowledge. The cell membrane is semi-permeable, which means that it retains certain electrolytes and other substances while it is freely permeable to others. By virtue of this property the cell contents exert an osmotic pressure which distends the cell with fluid. When a child is in full health and particularly after a seaside holiday, its flesh has a full firm feel which is quite different from that of oedema. The difference is that in the healthy flesh the fluid is contained in the tissue cells while in oedema it is in the tissue spaces—i.e., it is intracellular instead of intercellular. What has happened is that something has occurred to the cell walls that has enabled them to retain products to which they were previously permeable and so their osmotic pressure has risen with the consequent firm feeling typical of robust health. (It is of course also possible that the cells might have manufactured some new metabolite which had raised the osmotic pressure but on many grounds this seems unlikely particularly as the reverse process in shock, wherein the erythrocytes soon become permeable to potassium, which is then excreted, is well known.) Now the cell wall consists of what one might consider a very fine network made up of lipoids unravelled protein molecules and other bodies making the fine semi-permeable sieve, and it is also probable that there exist some larger spaces or "pores" and that it is through such pores that the viruses and the large molecules of toxins find entrance. If therefore we could in some way diminish these pores we might expect not only to exclude stray viruses but also toxins as well. In fact we should produce health. Can this be done?

I have written of the typical health of a seaside holiday but we know that clinically many of the benefits of such a holiday can be reproduced by liberal dosage with cod-liver oil or vitamins A and D and vitamin D at least is directly produced in the body at the seaside. These two fat-soluble vitamins are chemically closely allied with substances already known to exist in the cell walls and it is no far-fetched hypothesis to suggest that an ample supply of these vitamins

would, in fact, adsorb on to the existing cell wall network so producing that finer sieve which is required to enable the cell to retain other contents and so raise its osmotic pressure. It might even materially alter the physical, chemical, or electric formation of the larger pores. (When one gets down to molecular phenomena spatial, chemical, and physical or electrical conceptions largely merge into one another but in this case the process is most easily visualized as a net or sieve.)

Now I believe that chemotherapy on these lines—i.e., the injection of large doses of vitamins A and D—does give us just the effect that I have suggested as required to limit and inhibit the invasion of the body by viruses. I have mentioned in various communications, and do not here repeat, the effect of such injections on bacterial conditions—i.e., presumably on the large toxin molecules—and also their effect on cases of influenza in a letter which attained most unexpected publicity a publicity which has, I fear, prevented many doctors from testing the truth of what I then stated and have since proved many times over, not least in my own person. Most cases of measles are hardly bad enough to warrant giving the child an injection, but in those cases where for one reason or another I have given such injections (I use "dekadexolin," which was first made for me some sixteen years ago) the subsequent improvement has been rapid and marked. Chicken pox is even less in need of chemotherapy and I have only had two cases in which "dekadexolin" seemed justifiable. They were children in whom the chicken pox had got complicated with an impetigo with the result that nearly every pock became impetiginous—a distressing complication I have not seen recorded hitherto. To both these children I gave some "dekadexolin," and the way the infection cleared up was startling in its rapidity.

The simplest and easiest virus infection in which to study the effect of "dekadexolin" is herpes zoster, a condition so painful that the occasional discomfort caused by the injection is of little account. In my experience these cases all respond the same way. If the case is seen in the erythematous stage before any vesicles have formed, 2 ml of "dekadexolin" will abort it completely. Even after many vesicles have fully matured before the case is seen I find that administration of "dekadexolin" stops the threatening areas from developing as one would normally expect, and the whole disease runs a more rapid course. I have used "dekadexolin" very little for mumps but one adult to whom I gave it made such a rapid recovery that I doubted the diagnosis until his children later developed the disease, which he insisted I should treat in the same way and with the same happy results. I have had no opportunity to treat any cases of smallpox, but during the recent epidemic at Birkenhead I found that there was no known treatment for the very severe cases, so I wrote suggesting the use of "dekadexolin." My letter only finally reached the doctor in charge while he was treating the last severe case. I was told verbally that there was dramatic improvement for 48 hours after "dekadexolin" was started but then the improvement ceased and the child rapidly died. No further case occurred on which to try the treatment but apparently this was the only therapeutic measure which had been followed by any improvement in any such case and the child was very bad when it was instituted. I have not seen full notes of the case so I cannot comment on it further. I am well aware that one swallow does not make a summer, but it certainly seems a treatment worth further investigation.

All this may seem a meagre result for sixteen years' patient study. My reasoning may be wrong but of the correctness of my observations I am quite convinced and where I have been able to obtain controls or the opinion of better clinicians than myself I have availed myself of them. All too often however such help has been of little use. For example during the war I had two children brought to me with muscular pains and tenderness and weakness of one leg, just like a very early poliomyelitis. The obvious thing to do was to prevent development if I could, so I gave a dose of "dekadexolin" and arranged for the mother to take the child next day to the Manchester Children's Hospital. In each case the physician there could find no trace of anything wrong. Were they cured as according to my hypothesis they might well be, or was my provisional diagnosis wrong? These are the conditions under which a general practitioner works. I have just picked up straws as I found them in the course of a busy pra-

To me they all seemed to be blowing the same way. Many years ago they caused me to formulate the hypothesis I have restated above and all the further knowledge I have gleaned seems to me to suggest that we have here a method of general application which may point the way to as signal a victory over the viruses as has been achieved in other fields by the sulphonamides and penicillin. Even in bacterial infections it is a great adjuvant to their action, for viruses it seems at present our only practicable method.

I should not close this letter without a note about the administration of 'dekadexolin'. For some reason it does not act well unless it is given into the gluteal muscles, and more than 1 ml should not be given in one spot if pain is to be avoided and absorption hastened. Absorption is probably the great problem and not at all a simple matter. One might see even more marked effects if larger doses could be given intravenously as a very fine emulsion. The production of emulsions of the requisite fineness and stability presents great technical difficulties, though I have handled them and if the general thesis of this letter is correct they would no doubt be made generally available. There may be other substances more effective than vitamins A and D. "Dekadexolin" anyhow is perfectly harmless for I have given full doses to newborn babies as well as to the very aged. I only hope that this letter may stimulate research into the physicochemical effects of vitamins as well as their catalytic actions for it may well add to our control over illness and improve the health of our patients—I am, etc.,

Winsford, Cheshire

Calcification of the Thyroid Gland

SIR—I read Dr R T Shiggins's report (Dec 14, 1946, p 899) of calcification of the thyroid gland with interest. A few days later I saw a somewhat similar case which you may consider worthy of record.

CASE REPORT

An unmarried female patient aged 62 years was admitted to hospital complaining of frequent vomiting for 9 weeks prior to admission. She had had an operation for carcinoma of the right breast eleven years previously. Examination revealed a moderately wasted individual of neurotic temperament. There was a hard fixed mass attached to the mid-sternum and clinical signs suggesting metastatic carcinoma of lungs and mediastinum, abdomen, NAD.

Radiography confirmed the presence of widespread secondary deposits in sternum, lungs and mediastinum, and showed an oval calcified mass measuring 5.0 cm long, 3.0 cm broad, and 2.5 cm antero-posteriorly situated in the position of the left lobe of the thyroid gland.

Clinically the neck was normal on inspection, but palpation revealed a hard movable oval mass in the region occupied by the left thyroid lobe, which moved freely on swallowing. The patient showed no signs of abnormal thyroid activity or of local pressure.

In these circumstances, and having regard to her general condition, exploration was not indicated. The differential diagnosis would appear to include calcified lymph gland, calcified adenoma of thyroid, and calcification of the left lobe of the thyroid. In view of the standard measurements of a thyroid lobe—5 cm. by 3 cm. by 2 cm. (Gray's *Anatomy* 27th edition)—calcification of the lobe would seem the most probable. It is interesting to note that digestive symptoms were prominent in both patients, and, in each, abdominal investigation was negative—I am, etc.,

R.M.B.F. Christmas Gift Fund

SIR—I would like to thank through your *Journal* all who have generously subscribed to our Christmas Gifts Fund, it is a very great pleasure to be able to report that over £2,200 has been received.

On behalf of the Committee I warmly thank all the contributors and at the same time would like to express our gratitude to all the British Medical Association Divisions and Branches, Panel Committees and Medical Societies who arranged collections or who gave donations—I am, etc.

C LUTHER BATTESON
Hon. Treasurer
Royal Medical Benevolent Fund

Obituary

SIR ARNOLD LAWSON, KBE, FRCS

Sir Arnold Lawson, for many years ophthalmic surgeon to Middlesex Hospital, and afterwards a member of its consulting staff, died on Jan 19 at the age of 79. He was an exceptionally able ophthalmologist and a man of attractive personality. He was born in London in 1867, the son of George Lawson, FRCS, surgeon-oculist to Queen Victoria. One of the tasks he undertook early in his professional career was to revise and largely rewrite in 1903 the sixth edition of his father's notable textbook *Diseases and Injuries of the Eye*.

He went to Merchant Taylors School, and then began his training at the Middlesex Hospital, where he was Senior Entrance Scholar. His school career gave promise of future high achievement. He won the Hetley clinical prize in 1890, and later he became Senior Broderip Scholar. He qualified in 1891, and in the same year took the MD of the University of Brussels. In 1893 he became a Fellow of the Royal College of Surgeons. Paternal example, no doubt determined his choice of ophthalmology, and he had the great advantage of a period as clinical assistant to Sir John Tweedy at Moorfields. He joined his father in consulting practice at No 12, Harley Street, and continued at that address after his father's death and throughout his professional life. In 1896 he was appointed ophthalmic surgeon to the Paddington Green Children's Hospital, a position which he held until 1910 when he became assistant ophthalmic surgeon to his old hospital, the Middlesex, and full ophthalmic surgeon and lecturer on ophthalmology four years later. These posts he retained until his retirement under the age limit, when he was elected to the consulting staff. From 1900 to 1914 he was also surgeon to the Royal London Ophthalmic Hospital, and here again he was afterwards consulting surgeon. Other institutions with which he was associated as a consultant were the Royal Victoria Hospital and Home for Incurables, Putney, and Epsom College.

When St Dunstan's for War-blinded Soldiers, Sailors and Armenians was founded by the late Sir Arthur Pearson during the first world war, Lawson discovered there a form of service which engaged all his sympathy as well as his clinical skill. He served the institution not only as ophthalmic surgeon but as chairman of the Ophthalmic Advisory Board. His experiences among blinded soldiers were set out in a narrative, *War Blindness at St Dunstan's* published in 1922. He also served other war institutions including the King Edward VII Hospital for Officers. In 1939 he was appointed part-time civil consultant (ophthalmic) to the Royal Navy.

Sir Arnold Lawson took a conspicuous share in the advancement of ophthalmology in general. He stood aside from the semi-political aspects of ophthalmic service but he did a great deal to advance the subject on its scientific and clinical side. He was a prominent figure for nearly half a century in the Ophthalmological Society of the United Kingdom, of which his father was an original member. For very many years Sir Arnold served as its treasurer with scrupulous care. The Society had his real affection, and it was due to him and the late Treacher Collins and some others that it kept its identity and refrained from amalgamation in the Royal Society of Medicine. But he was an active member of the RSM and at one time president of its Ophthalmological Section. He also served as one of the honorary officers of the Section of Ophthalmology at Annual Meetings of the British Medical Association in 1899, 1906 and 1927. At the meeting in Edinburgh in

(Elliott and Fry Ltd)

the last of those years he read a noteworthy paper on the value of antiseptics in modern ophthalmic surgery

He was a most careful operator, and yet in some ways unconventional. While he never advocated any neglect of pre-operative precautionary measures, he thought the routine use of antiseptics in eye work in some respects proceeded from a misconception. He recalled that he was the first surgeon at Moorfields to adopt an overall, and that his revered teacher, Sir John Tweedy, right up to his retirement used his index finger to effect counter-pressure and to prevent the eye rotating inwards when making his cataract section, instead of employing fixation forceps. The results obtained compared quite favourably with those seen in later years when masks, gloves, overalls, and all the other appurtenances were, rightly, held to be *de rigueur*. Lawson himself entirely gave up the use of gloves in intraocular and strabismus operations, but he was extremely careful that no part of any instrument other than the shaft or handle should be touched by his fingers. He was accustomed to soak his hands in spirit after scrubbing, and to have a bowl of spirit by him during the operation so that he could rinse his hands at any moment.

What appears to have been his first contribution to the literature of ophthalmology was an account in 1897 of a case of orbital cyst. His father had operated and removed the cyst, and had then handed it over to his son for examination and report. From that time onwards the *Transactions* of the Ophthalmological Society contain frequent contributions from him not only set papers but remarks in discussions, generally brief but always pointed by personal experience. He described his method in operating on intraocular tumours, his employment of Thiersch grafts for xerophthalmia in the early years of this century, and his treatment of corneal ulcers by quinine. He collaborated with Sir James Mackenzie Davidson in trying radium treatment for various external diseases of the eye. Quite early in his career he published the report of an exhaustive inquiry he had made into the bacteriology of the normal conjunctival sac, and the results of that investigation, he claimed, safely guided him through many years of operative work. Apart from the revision of his father's standard work, Arnold Lawson did not write a book but articles by him on such subjects as cataract, affections of the ocular muscles, diseases of the iris and ciliary body, and sympathetic ophthalmia are to be found in various medical encyclopaedias.

He married in 1904 the eldest daughter of Andrew Clark, F.R.C.S., honorary surgeon to the King, and had two sons and one daughter. His knighthood was conferred upon him in 1920. Perhaps his last services to the profession were in connexion with the Royal Medical Benevolent Fund. He was elected president in 1945, on the death of Sir Thomas Barlow.

Dr FLORA NIHAL-SINGH died at her home in Pebmarsh, Essex, on Dec 19 at the age of 64. Miss Singh was the daughter of the first native canon of Lucknow and was born in India. She was educated at the Calcutta Medical College and the London School of Medicine for Women, qualifying M.R.C.S., L.R.C.P. in 1917. She had been a senior house-surgeon at the Essex County Hospital in Colchester before she moved to Pebmarsh, where she built up an extensive practice. She was greatly interested in the work of the British Red Cross Society and was an active member of the Colchester Medical Society. She had been a member of the British Medical Association for twenty-six years.

Dr JOHN YOUNG of Bishop's Stortford, died at the age of 81 on Dec 20. A student of Guy's Hospital, and later a house-physician and resident obstetrician there, he took the M.R.C.S., L.R.C.P. in 1891, the M.B., B.S. in the same year, and proceeded M.D. three years later. He had been in general practice for many years at Stamford Hill, in North London, before he moved to Bishop's Stortford in 1919. Though in nominal retirement, he acted as medical officer to Bishop's Stortford College, of which he was later a governor. In 1922 he was elected to the urban council and also to the old board of guardians. This was the beginning of a long period of public work. He was chairman of the visiting committee of the Bishop's Stortford board of guardians and a member of the board of management of the local hospital and of the East Herts Joint Hospital Board. He had been an elder and former deacon of the Congregational Church. Dr Young finally retired from the local council after having served for twenty-four years. Among his many other interests was the local

Beekeepers' Association, of which he was treasurer. He was also president of the local Conservative Association when that body presented him with an illuminated address on the occasion of his eightieth birthday.

Dr MARY HELEN MACGREGOR GORDON, of Newport, Monmouthshire, died on Dec 20. Dr Gordon was a daughter of the late Rev William Gordon of Arnshean, Barrhill, Ayrshire. A student of Edinburgh University, she qualified M.B., Ch.B. in 1921, and took the D.P.H. a year later. Early in 1924 she became assistant medical officer to the Monmouthshire County Council, and was also an assistant physician in the dermatological department of the Royal Gwent Hospital. She was secretary, and a former president, of the towns Caledonian Society, and had been a member of the British Medical Association for twenty-one years.

Dr Margaret M. Basham writes: Mary Gordon was much beloved in this county and will be greatly missed by a wide circle of friends and patients. Among other things, she was in charge of the V.D. clinics at the Royal Gwent Hospital for the women and children of the county. She always gave of her best and was always ready to help others.

Dr JOHN LISSAUER, who died on Dec 24, 1946, was educated at Munich, Heidelberg, and Berlin. He had specialized in paediatrics, but he had the misfortune to be a Jew in pre-war Germany. After a brief period in a concentration camp at the end of 1938, he managed to reach this country in February 1939. Later he became assistant medical officer of health and assistant school medical officer at West Hartlepool. His wife, who survives him and is also a doctor, joined the Middlesbrough school medical service at much the same time.

Dr CHARLES LLEWELLYN LANDER, who was 73, died on Christmas Day at Gillingham, Dorset, where he had been residing since his retirement from practice in Plymouth in 1934. He had been consulting surgeon to the Prince of Wales's Hospital, Devonport, and had served on the surgical staff there for some thirty-five years. A member of the British Medical Association since 1902, he took a keen interest in medico-political affairs. He had been chairman of the Plymouth Division and representative at the Annual Representative Meeting in Glasgow in 1922. He was also an active member of the Plymouth Medical Society. In the 1914-18 war he served with distinction, and was awarded the M.C. and the D.S.O. while in command of the 2/3 South Midland Field Ambulance. He was a J.P., and for many years a city councillor and vice chairman of the public health committee. Although devoted to the voluntary hospital he firmly advocated the introduction of the municipal hospital system and foreshadowed mutual benefits from close co-operation. A first class chess player he reached the semi-final of the B.M.A. Melbourne Chess Cup competition in Plymouth in 1938. Of a kindly and sincere disposition he was beloved by his patients, and his opinion, in debate or at the bedside was always appreciated by his colleagues, who will ever remember him with the highest affection and esteem. Dr Lander is survived by his widow, one daughter, and two sons. One son, Dr Oswald Lander, practises in Plymouth.

Dr ALEXANDER JOHN GIBSON died in a Glasgow hospital on Dec 27, 1946, at the age of 56. It was with great regret that the members of the Ayrshire Division of the British Medical Association learned of the death of Dr Gibson, the only son of the late Mr and Mrs James B. Gibson of Baillieston, Glasgow. Dr Gibson had had a distinguished career. He served in the first world war, gaining the D.S.O. and retiring with the rank of lieutenant-colonel. Between the wars he was in active practice in the Royal Burgh of Irvine and took a leading part in the activities of the Ayrshire Division. After serving for many years as a member of the committee, he was elected chairman of the Division in 1932, continuing in office until 1934. Dr Gibson had a very attractive personality, and anything that he undertook always seemed to move smoothly. He was a first rate golfer and enjoyed membership of the Bogside course. He represented the Division in the competition for the Treasurer's Cup in 1936. In 1939 Dr Gibson rejoined the R.A.M.C. and was appointed A.D.M.S. of the 15th Scottish Division. Later he served in the Northumbrian district and overseas, in command of the 12th General Hospital in Palestine, retiring in 1945 with the rank of colonel. Dr Gibson was twice married and to his wife and his two daughters the Division has already expressed sincere sympathy.

Dr GEOFFREY WARD THOMPSON died at his home in Scarborough on Dec 27, 1946. He was educated at Rossall School, Christ's College, Cambridge, and St Thomas's Hospital. After qualifying in 1893 he was house surgeon and house physician at St Thomas's, and later house-surgeon at the hospital for

SUPPORT WITH COMFORT

Abdominal Ptois in all its forms can be reliably treated by the Curtis Abdominal Support No. 1. It gives direct anterior posterior pressure but has no undue constricting effect on the lower abdomen and assures complete freedom of hip movement, in other words, it gives gentle pressure and firm support only where it is needed. Lasting comfort in wear is assured at all times by the high standard of workmanship and finish. This is one of the many types of Curtis Product, whose use is recommended by the Medical Profession.

BRIDGING THE GULF

IN ARTIFICIAL FEEDING

For more than forty years COW & GATE Milk Foods have successfully bridged that dangerous gulf in infant feeding when breast feeding is impossible or inadequate and the child's delicate digestion needs especial consideration.

Normally medical opinion in such cases directs that a baby should be introduced to artificial feeding by means of a half cream milk.

COW & GATE HALF CREAM MILK FOOD bridges the gulf between breast and full artificial feeding. The transition period may be artificial and Cow & Gate Half Cream provides a most satisfactory means of introducing complementary feeding. Should immediate change to full artificial feeding be necessary Half Cream Food ensures a minimum disturbance of infant metabolism.

THE FOOD IS FORTIFIED BY THE ADDITION OF VITAMIN D 320 I U per OUNCE AND IRON 1 mgm per OUNCE

Particulars of this and other Cow & Gate preparations for specialised infant feeding will be gladly forwarded on request

COW & GATE LTD
GUILDFORD SURREY

sick children in Nottingham. He settled in Scarborough in 1895 and was in general and consultant practice there until his retirement in 1939. Dr Thompson was medical officer to Bramcote, Queen Margaret's, and Queen Mary's Schools, and medical referee for the Ministry of Pensions, 1919-39. He joined the R A M C in 1914, and served in Gallipoli, Mesopotamia, and India. He was an active member of the British Medical Association for fifty-one years, serving on all the committees of the local division and holding office as chairman in 1913.

A colleague writes: Geoffrey Thompson's interests were so wide and varied that it is difficult to catalogue them in a brief notice. They can best be summarized as primarily, his family and his profession, and then all forms of sport. In his youth he was a first class performer at cricket, soccer hockey, and athletics, and this interest in sport was retained throughout his life. In 1934 he was president of the Scarborough Cricket Festival. Thompson was a true Christian in the highest sense of the word, and his life, professional and otherwise bore eloquent testimony to this fact. He was loved and respected for his professional skill, his kindness, his unselfishness and for those characteristics that a lifetime of devoted service must bring. He will long be remembered in Scarborough as a good physician and a good man.

Dr WILLIAM HAROLD WHITE died at his home in Hindhead, Sussex, on Dec 29 at the age of 64. A son of the late Rev Samuel White, he was educated at the Clergy Orphan School at Canterbury and at St Thomas's Hospital. He qualified in 1917 and did a year's service in the R A M C. He had been a house surgeon at the Royal Portsmouth Hospital, and a house-physician at the General Lying-in Hospital in York Road before he began to specialize in obstetrics. Dr White, with his partner, founded a maternity home at Stonefield Blackheath, London, SE2. He was a keen advocate of vegetarian diets with a high proportion of uncooked food, and insisted on the special value of this regime for expectant mothers. During the recent war the main part of his maternity home was evacuated, but Dr White stayed on at Stonefield to attend patients who were unable to leave this much-bombed area. His death came only a few months after his retirement to Hindhead. He leaves a widow, three sons, and two daughters.

Dr JOHN SAMUEL MARTIN who died at the age of 82 on Dec 29 at St Margaret's Bay Dover, had been a well-known general practitioner in Kidderminster. A native of Co Down, Dr Martin was a student of Queen's College, Belfast and Surgeons' Hall, Edinburgh, and he took the Scottish triple qualification in 1892. He first of all acted as assistant to his brother, James Martin, who was medical attendant for the Kidderminster medical aid association. When his brother resigned in 1895, Dr John Martin took over as senior medical officer a position he held until 1914. During the 1914-18 war he served with the R A M C, and was at one time in command of No 4 Ambulance Train. He returned to practise in Kidderminster after the war but moved to Dover on his retirement.

Dr HERBERT STANLEY-JONES died on Dec 29. Dr Jones was an Australian who took the M R C S, L R C P in 1903 as a student of Guy's Hospital. He graduated MB B S in 1904 and was for a time house-surgeon to the Hospital for Sick Children at Great Ormond Street. He was in practice in Bournemouth until the outbreak of war in 1914 when he served in the R A M C. After demobilization he entered into partnership with Dr A. H. Burnett, but later he opened a practice of his own in Southampton. He did a great deal of work for the Ministry of Pensions in Southampton and was also well known as an examiner for some of the insurance companies. He had contributed papers on the physiology of the thyroid and the suprarenals to the medical press and he was an active member of the Southampton Medical Society. He had been a sick man for some time but he continued in active practice until barely a month before his death.

On Dec 31, 1946, ARTHUR MANTELL DALDY died at his home in Hove, Sussex. He was 77 years of age. Arthur Daldy was a student at Guy's Hospital and he qualified MB B S in 1892, winning the gold medal in medicine after taking the M R C S, L R C P in 1891. He proceeded MD in 1893 and was elected F R C S a year later. Before coming to Hove in 1905 Dr Daldy had practised for years in Surbiton. Throughout his successful medical career, for many years as a general practitioner and latterly as an ophthalmic specialist, he placed his skill and energies unstintingly at the service of the community. During the 1914-18 war he served in the 2nd Eastern General Hospital with the rank of captain R A M C. In 1914 he was appointed honorary surgeon to the Sussex Eye Hospital

and on his retirement in 1929 was elected consulting surgeon to the hospital. From 1920 to 1945 he was ophthalmic specialist to the Hove Education Authority. He had been a member of the British Medical Association for over fifty-five years, and was a past vice-president of the Richmond Division and formerly secretary and treasurer of the Brighton Division for a period of seven years. His high sense of duty, his high ethical standards, and his unfailing kindness and gentleness had endeared him to patients and colleagues alike and a large circle of friends in all walks of life will mourn his passing. He is survived by his widow, a son, and a daughter.

A colleague writes: By the death of Arthur Mantell Daldy the profession in Hove has lost one of its oldest and most respected members. In 1922 Dr Daldy became hon. secretary and treasurer of the Sussex Branch. On his retirement from this office he was presented with a testimonial from his colleagues in appreciation of his valuable work for the Branch over many years. His work as Branch secretary brought him into contact with doctors all over Sussex, and his charm of manner and upright personality brought him a host of friends among them. At the Annual Meeting in Brighton in 1913 he acted as one of the secretaries of the Ophthalmological Section. Dr Daldy was an able, courteous, and unassuming man, never seeking the limelight or pushing forward his claims. It can be truthfully said of him that in spite of his rather retiring manner he won the respect, admiration, and friendship of his fellow doctors, who deeply regret the loss of a valued colleague.

Dr WILLIAM HARTLEY THOMPSON who died at the age of 81 was buried at All Saints' Church, Bradford, on Jan 3. Dr Thompson was a student of Leeds University and qualified M R C S, L R C P in 1891. He had been a house-physician at the Leeds Infirmary before starting practice in Bradford. He was one of the original members of the medical staff of St. Luke's Hospital, from which he retired as senior physician in 1939. Dr Thompson was also honorary physician to the Bradford Children's Hospital, and after serving as a major in the R A M C during the 1914-18 war he became neurologist and medical specialist for the Ministry of Pensions. He contributed several short articles to this *Journal*, notably those on adenocarcinoma of the breast in a girl of 11 years, and strangulated inguinal hernia in an infant of 29 days. Dr Thompson had been in partnership with Dr W. G. Burnie, and his death will be regretted by all his many friends and colleagues in Bradford.

Mr CHRISTOPHER TREDWELL HOLFORD, consultant surgeon to the General Infirmary, Burton-on-Trent, died suddenly at Triverton, Devon, on Jan 4. Having been forced to retire by ill-health brought on as a result of his long period of strenuous and untiring effort as honorary surgeon to the Burton Infirmary, it was his unfortunate lot to be unable, owing to war conditions, to settle down to enjoy the quiet of Devon and the delights of angling. These were his joys. These he had looked for as the just relaxations of a man who had worked unceasingly and without complaint to the benefit of thousands in the area the infirmary served. Mr Holford was educated at Winchester and from there went to St Thomas's. He qualified M R C S, L R C P in 1902, and afterwards held surgical appointments at St Thomas's at Warneford Hospital in Leamington, and at the Royal Infirmary, Hull. He took his F R C S Ed in 1904. He then came to Burton and was in general practice until 1938, but it was as honorary surgeon to the infirmary that he was best known. His tirelessness, his unfailing consideration for patients, and his great technical skill as a surgeon soon made his name known, respected, and loved throughout the area served by the hospital. He overworked himself badly, but built up the infirmary to the high standard of efficiency that it now possesses. There will be his most lasting memorial—the new nurses' home when opened being given the name of Holford House. Throughout this busy life he gave service wherever it was required. During the years 1914-18 he was surgeon to the V A D Hospital at Burton. He was also consultant surgeon to the Yoxall Barton and Ashby cottage hospitals. A member of the British Medical Association since 1903, he was a representative at the Annual Representative Meeting in 1911, and was president of the Staffordshire Branch in 1920-1. He was also chairman of the Burton Panel and Medical Committee for many years. He was made a Justice of the Peace of the county borough of Burton-on-Trent in 1940. Christopher Tredwell Holford was a man who will be greatly missed by all who knew him—by his fellow practitioners, by his own patients and by the many who passed through his careful hands during his long office as honorary surgeon to the Burton Infirmary. A quiet, tireless, simple, honest man, he bent his whole attention towards helping those who required his aid and in the cause of the hospital he loved so much—N J C.

Dr WILLIAM MILL died on Jan 5 at St Andrew's Lyne Regis in his ninetyeth year. He was the son of the late David Mill, of Tavistock, Devon. His medical studies were pursued at St Mary's Hospital, London, where he qualified MRCs in 1882 and LRCP and LM in 1883. He was in general practice for many years at Wigan, but retired from this soon after the 1914-18 war and thereafter acted as locum tenens. This work he did regularly until 1942, in which year a fracture of the leg put an end to his physical capacity to continue. He was then 85, and his gallant struggle to earn a living excited the sympathy of both the Royal Medical Benevolent Fund and of Epsom College when he was obliged to apply to them for help which was very liberally forthcoming from both organizations. Dr Mill married Miss Etty Frederica Brooks in 1885. She died more than thirty years ago, leaving no family.

We announce with regret the death at the age of 75 of **Dr JOHN VINCENT SHAW** of Hereford. Dr Shaw was born in Colcar, near Huddersfield in 1871, and he qualified MB ChB at Leeds in 1895. He was in general practice in Yorkshire and later in Derbyshire before he settled in Hereford in 1922. Dr Shaw was always keenly interested in local affairs and particularly in housing conditions. He served on the Hereford City Council for several years and was elected mayor in 1934. He became an alderman in 1941. It was also in 1934 that he won his seat on the Herefordshire County Council. He stood for Parliament as a Liberal candidate in 1929, and again in 1935 it was suggested that he should stand for the Torquay Division, but he withdrew his candidature in order to devote more time to his municipal activities in Hereford. Dr Shaw had been a member of the British Medical Association for forty-eight years and he was also an active honorary secretary of the Herefordshire Free Church Council. He retired in 1930 but during the war years he took up practice again at Chippenham. Friends and colleagues in Hereford will all regret the passing of an invigorating personality who made an outstanding contribution to the medical public social, and religious life of the county. Dr Shaw continued his many duties as an alderman and as a county councillor up to three days before his death from acute pneumonia on Dec 22. Almost to the end he retained the buoyant optimism and cheerful disposition which had endeared him to the people of Hereford.

CATHERINE MABEL EDGERLEY was one of the first few women to qualify in Scotland. She took the LRCP, MRCs at Edinburgh and the LRFPS of Glasgow in 1894. Educated at Edinburgh and in Germany, she was at one time assistant medical officer at the West Riding Mental Hospital at Sheffield. She was also sugeon-in-charge of the Otley Division of the St John Ambulance Brigade. She contributed an article to the *Journal of Mental Science* in 1900 on the glioma of the corpus callosum. Her medical work came to an end, however, with her marriage in 1907 to Dr Samuel Edgerley, who survives her. From then onwards perhaps her main interest was in the Bronte Society, and in 1931 we published in this *Journal* a note of hers on the eyesight of the Brontes and in the following year a discussion of the causes of death in this remarkable family. She was for seventeen years the secretary of the Bronte Society and a frequent contributor to its *Transactions*.

Dr FREDERICK CRICHTON MATTHEW will be greatly missed in Cornwall by a small circle of doctors who knew him well and by a large number of the general public who knew him intimately, chiefly in his home town of St Ives. Dr Matthew qualified in Edinburgh in 1900, took the FRCS Ed two years later and proceeded MD in 1903. He was a resident surgeon at the Edinburgh Royal Infirmary for a brief period. He came to Cornwall in 1905 before the motor car had invaded the quiet, winding streets of this pleasant little Cornish town. From that time onward with one break during the first world war, when he served as a captain in the RAMC, he worked for the people of St Ives with a devotion which can seldom have been surpassed. He rarely took a holiday, and when he did he was always impatient to get back to the job. He had few hobbies or interests outside his professional work, and in later years he had little interest in medical politics. Despite his academic distinctions he remained a general practitioner and did not practise as a surgeon. Though he was shrewd in judgement and accurate as a diagnostician his sense of devotion to duty and the affection he evoked in the warm-hearted Cornish people among whom he worked were what most impressed those of his colleagues who came to know him. The profession in Cornwall will mourn the loss of a loyal friend and great gentleman.

The Services.

HRH the Prince Regent of Belgium has conferred the Chevalier of the Order of Leopold II with Palm and Croix de Guerre, 1940 with Palm upon Capt A R Turnbull and Lieut A N Wright, RCAMC, in recognition of distinguished services in the cause of the Allies.

The Bronze Star Medal of the USA was presented to Major H G McQuade, RAMC at the US Ambassador's residence in London on Jan 3 by Major Gen Bissell (Military Attaché), for meritorious achievement in connexion with military operations against the enemy in Italy from April 9 to 29 1945. The Efficiency Medal (Territorial) has been awarded to Capt (Hon Major) G W Thomas Lieut (Hon Capt) C J Stokes and Lieut R D Sim, RAMC, and Capt (Temp Major) Janet E Leng, employed with the RAMC.

DEATHS IN THE SERVICES

Col JOHN HEATLY-SPENCER CBE, MD, FRCP, who died at Kew on Dec 31, 1946, aged 68, was a distinguished member of the Royal Army Medical Corps. He was educated in New Zealand and at Charing Cross Hospital and qualified in 1906 at the London University. He was elected a Fellow of the Royal College of Physicians of London in 1935, after passing the MRCP in 1921. He obtained a commission in the RAMC in 1906 and served in India and in various parts of Europe in the first world war. In 1923 he took the DTM&H, Cambridge and held the important post of professor of medicine at the Millbank RAMC College from 1929 to 1934. He then became professor of tropical medicine at the College and consulting physician to the British Army until 1937 when he retired. He established a reputation as a sound physician, which led to his election to the coveted fellowship of the Royal College of Physicians—a position which few Army Service officers have attained. He was appointed Hon Physician to the King in 1935-7. For his long and meritorious service he was awarded the OBE in 1927 and the CBE in 1937. In 1928 he had changed his name from John Heatly Spencer to John Heatly as Colonel R A R of O and as a member of the Ministry of Pensions tribunal in 1944. He was also a member of council of the British Medical Association in 1939-40. He leaves a wife and two daughters to mourn his loss.

Col LEWIS AUGUSTUS CLUTTERBUCK ASC (retired), died on Jan 2 at Falmouth at the age of 92. He had an unusual career, for after being educated at Sydney College, Bath he obtained a commission in the Army in 1872 and saw active military service in the Sudan in 1882, held various staff appointments, and retired from the Army after thirty years' service. He then turned his attention to the study of medicine as a hobby. He qualified at Edinburgh in 1899 and soon after in Glasgow and Dublin. In 1904 he obtained honours in the Durham MB, BS, and in the following year he passed the MRCP. Yet he never practised medicine except for serving on recruiting and pension assessment boards during the 1914-18 war. He lived at Falmouth and was interested in special treatment clinics, orphanages, and similar institutions, up to very recently. He will be missed by his many friends.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on Dec 14, 1946, the following medical degrees were conferred:

BM—J B Loudon H D Leggatt M G D Davys Alison M Miles

ROYAL COLLEGE OF SURGEONS IN IRELAND

An intensive postgraduate course in surgery will be conducted in Dublin from April 14 to June 12, and will consist of afternoon clinical sessions at the main teaching hospitals with correlated demonstrations in the anatomy and pathology departments of the College. The fee for the course is £21 and, as numbers will be restricted, those intending to join should make early application to the Registrar of the College Prof W N Rae DSc St Stephen's Green, Dublin from whom detailed particulars can be obtained.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Mr Philip H Mitchiner will deliver a lecture on "Surgery in Two Wars" in the Hall of the Faculty 242 St Vincent Street Glasgow, on Wednesday, Jan 29 at 4 pm.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan 4

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

* Includes primary form for England and Wales, London (administrative county) and Northern Ireland

‡ Includes puerperal fever for England and Wales and Eire.

In *England and Wales* a large increase in the prevalence of infectious diseases was recorded during the week. There was a rise in the incidence of measles 3,755, whooping-cough 881 acute pneumonia 504, scarlet fever 218, and diphtheria 620.

The largest increases in the notifications of measles were in Lancashire 799, Warwickshire 464, Yorkshire West Riding 273 Cheshire 227, Middlesex 207 Staffordshire 171 Nottinghamshire 157, London 130 and Derbyshire 115. The increase in cases of whooping-cough was larger in the North, and especially in Lancashire 137, Staffordshire 65, Warwickshire 51 and Yorkshire West Riding 45. The only variations of any size in the local trends of diphtheria were increases in incidence in Essex 12 and Lancashire 10.

A fresh outbreak of dysentery was recorded in Gloucestershire, involving 12 persons, the only other important centre of infection was Lancashire 15.

Small increases in the incidence of scarlet fever were recorded in most areas of the country but no large local variations were reported. The chief increases in the notifications of acute pneumonia were Lancashire 70, Essex 45, and London 35.

In *Scotland* infections decreased in prevalence, in contrast to the experience of England and Wales. There were falls in the notifications of whooping cough 78, scarlet fever 53, and measles 18, the only increase of any size was cerebrospinal fever 9 and this rise in incidence was confined to the south-eastern and western areas.

In *Eire* the chief change in the trends of infectious diseases was the decrease in measles only 28 cases being notified.

In *Northern Ireland* a large increase occurred in the measles epidemic in Belfast C.B. notifications increasing from 325 to 758. An increase of 26 in the notifications of whooping-cough was also reported from this city.

Week Ending January 11

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1 058 whooping-cough 1,928, diphtheria 232, measles 10,223 acute pneumonia 1,264 cerebrospinal fever 56, dysentery 87, acute poliomyelitis 14, paratyphoid 4 typhoid 4.

Medical News

The Cambridge University Medical Society is to celebrate its twenty fifth anniversary by a silver jubilee ball to be held at Grosvenor House, Park Lane W, on Thursday, March 27, when there will be dancing to Sydney Lipton's orchestra from 8 p.m. to 1 a.m., a supper, and a cabaret. The cost of double tickets (strictly limited to 225) for life members is £3 13s 6d and to non-members £4 4s. Application forms may be obtained from the Ball Committee of the society at Trinity Hall, Cambridge.

A general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, Cavendish Square, W, on Saturday Jan 25, at 2.30 p.m., when Prof J. W. McLeod will give an address on "Smear and Cultural Diagnosis in Gonorrhoea".

A meeting of the Nutrition Panel of the Society of Chemical Industry will be held at the Chemical Society's rooms (Burlington House, Piccadilly, W) on Wednesday, Jan 29, at 6.30 p.m., when Prof E. Capstick will present a paper on "The Nation's Milk Supply and its Best Use". A discussion will follow. Members of the Food Group are invited to attend.

The next meeting of the British Branch of the International League Against Epilepsy will be held at the National Hospital Queen Square, London W.C., on Friday Jan 31 at 10 a.m. Papers will be read and discussed in the morning and in the afternoon. Luncheon arrangements have been made with the Royal Hotel Woburn Place, W.C.

The second International Congress of the International Academy of Legal and Social Medicine will be held at Brussels and Liège from June 25 to 28, and will be divided into five sections, legal medicine in its application to crime, social medicine, industrial medicine medico legal and social psychiatry, and scientific police. The official languages will be English and French. Those who wish to present reports or read papers should notify without delay the president of the Congress Prof Dr M. De Lact, Faculté de Médecine 7 Rue de la Gendarmerie Brussels or one of the general secretaries Prof Dr P. Moureau (47, Rue Villotte Liège) or Prof Dr F. Thomas (23, Kluykensstraat, Ghent).

Sir Ernest Cowell was last week invested by the French Ambassador with the insignia of the Legion d'Honneur and the Croix de Guerre with palms, which was awarded in 1943.

A new quarterly publication entitled *The British Journal of Cancer* is to be published as the official organ of the British Empire Cancer Campaign. The annual subscription is £2 2s, and it is hoped that the first number will appear at the end of March. The journal is for the publication of original communications concerning the causes, distribution, symptoms, pathology, and treatment of malignant disease and allied conditions. Papers upon clinical, bacteriological, biochemical, pharmacological, physiological, radiological, serological and other subjects, therefore, would be acceptable when related to this subject. The publishers are Messrs H K Lewis and Co., 136, Gower Street, London, WC1.

Since the Galton Laboratory Serum Unit (Medical Research Council), formerly at Cambridge, closed in May, 1946, Dr R R Race, the former director, has moved to the Lister Institute, London, where he is in charge of the new Blood Group Research Unit of the Medical Research Council. Dr A E Mowbray, who formerly assisted Dr Race, has become director of the new Blood Group Reference Laboratory of the Ministry of Health. This laboratory, which is part of the Ministry of Health Blood Transfusion Service, is also situated at the Lister Institute, and will provide grouping serum and investigate clinical blood group problems. The juxtaposition of these two laboratories will be of great mutual benefit and ensure the close association of the theoretical and practical sides of this subject. Hospitals and doctors requiring grouping serum should, in the first instance, apply to their local Regional Transfusion Centre, through which grouping serum will be issued.

Col Lawrence Whitaker Harrison, C.B., D.S.O., M.B., Ch.B. Glas., F.R.C.P. Ed., has retired from the staff of the Ministry of Health, to which he has been adviser on venereal diseases since 1919. Col Harrison has been associated with the control of venereal diseases in England and Wales for nearly half a century. In recognition of his work the American Social Hygiene Association awarded him the William Freeman Snow Medal for 1946. This annual award "for distinguished service to humanity" consists of a medal replica of the portrait plaque which was presented in 1937 to the distinguished American doctor, William Freeman Snow, to mark his fortieth year of service in the field of public health and social hygiene.

King Edward's Hospital Fund has received a further instalment of £75,000 from the Nuffield Trust for the Special Areas. In founding this Trust Lord Nuffield provided that any sums that might be available by way of repayment of loans or otherwise from his Trust for the Special Areas should pass to King Edward's Hospital Fund for London. A total sum of £575,000 has now been received, the first £250,000 of which was, at Lord Nuffield's request, allocated to Guy's Hospital.

After fifty years devoted to the advancement of medical publishing, including the issue of the *Medical Directory*, Mr A W Churchill has decided to retire from the position of managing director of Messrs J and A Churchill, Ltd. He will remain on the board as vice-chairman, so that the business, which was founded by his grandfather in 1825, will continue to benefit from his skilled help and advice. His place as managing director has been taken by Mr J Rivers, who joined the firm forty years ago.

The Medical Research Council have appointed Dr S T Cowan (formerly of the University of Manchester) to succeed Dr R St John Brooks as Director of the National Collection of Type Cultures of Micro organisms. The Collection continues to be housed at the Elstree establishment of the Lister Institute of Preventive Medicine but will be moved to the Central Public Health Laboratory at Colindale as soon as accommodation there is available.

The Association of Scientific Workers, 15, Half Moon Street, London, W1, of which Prof P M S Blackett, F.R.S., is president, has informed us that its membership is open to doctors and especially to laboratory workers. Its present members include chemists, engineers, agriculturists, and others.

In view of the increased supplies of pharmaceutical livers now available it has been decided to revoke the Liver Extract (Regulation of Use) Order, 1945, and the necessary Order has now been issued. The effect is that both injectable and oral preparations of liver may be freely manufactured and used in treatment.

Maj Gen Sir Alexander Ingram, F.R.C.P., has been appointed Director of Postgraduate Studies in Medicine by the Postgraduate Board for Medicine in Edinburgh. The University Medical School and the Royal Colleges of Physicians and Surgeons of Edinburgh have co-operated to establish the Board.

Prof Olympio Da Fonseca, of Brazil, who was head of the tropical diseases section of the recent Pasteur Commemoration conference in Paris, is on a short visit, arranged by the British Council, to this country, and will meet British colleagues and visit institutions concerned with tropical medicine in London and in Liverpool.

At the invitation of the Central Council of Physical Recreation and the British Council a party of French medical specialists has arrived in England to study British methods of physical recreation with a view to their possible adoption in France.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Effects of Tobacco

Q—Does tobacco smoke contain any injurious products and has it any demonstrable carcinogenic activity? Is the pathogenesis of the following conditions related to the abuse of tobacco: retrobulbar neuritis, arterial disease including hypertension, cardiac disturbances, peptic ulceration, leukoplakia and carcinoma of the lip, tongue, stomach and bronchus? If so how may heavy smokers avoid such unpleasant sequelae? Can tobacco stains be removed from the teeth without a visit to the dentist?

A—In addition to nicotine, cigarette smoke contains hydrocyanic acid, pyridines, ammonia, and carbon monoxide. The ammonia is responsible for some of the irritation of the respiratory passages which many confirmed smokers suffer, the pyridines are said to cause the gastro-intestinal distress of the neophyte. Tars are formed when tobacco is heated, but these are only weakly, if at all, carcinogenic when painted on the skin of mice. It is difficult to assess the extent to which tobacco can be blamed for the disorders mentioned. Publications on the subject often have a partisan flavour, and appear to be animated by the spirit which led the earlier Czars to transfix the smoker's nose with the stem of his pipe before beheading him. Tobacco amblyopia (retrobulbar neuritis) is traditionally said to occur in smokers of shag, it has been claimed that smoking causes a retinal vasoconstriction. Others hold that this type of visual disturbance is seen only in smokers who are also heavy drinkers, and that it is due to a deficiency of vitamin B₁. It has been stated that vision returns to normal when thiamine is given, even though the consumption of tobacco and alcohol is undiminished.

There is no evidence that hypertension is related to tobacco but thrombo-angiitis obliterans does seem to be more common in heavy cigarette smokers. It has been shown that smoking a cigarette is accompanied by a fall in the skin temperature of the extremities due to vasoconstriction. In some persons heavy smoking is associated with premature contractions, but there is no reason to suspect that it has any permanent effect on the heart. Peptic ulceration does not appear to be more common in heavy smokers nor does smoking affect this disorder adversely. There is no evidence for believing that carcinoma of the stomach or bronchus can be attributed to tobacco. Many *ex cathedra* pronouncements impugn it as a cause of cancer of the lip and tongue, it must be regarded as an irritant in these situations and thus as a possible aetiological factor. The only way in which heavy smokers can avoid these dangers many of them probably hypothetical, is by smoking less. Once the teeth have become discoloured there is no satisfactory alternative to a visit to the dentist.

Fluorine, Chlorine, and Milk

Q—Why is extra milk given to workers with fluorine? Is it likely to be of value to workers with chlorine?

A—There are two reasons for giving milk to workers with fluorine: (a) to take up acid in the gastric contents and therefore act as a demulcent against gastritis, (b) to prevent decalcification of the bones, by providing extra calcium. The first of these functions would apply to chlorine workers, but not the latter.

Delay in Delivery of Twins

Q—A multigravida aged 35 gave birth after five hours labour to a healthy full-term male infant. I was called six hours later on account of the presence of a previously undiagnosed twin. The second twin a healthy female infant was delivered 106 hours later. Is so long an interval rare? What is the correct management of twin delivery?

A—An interval of several hours, days, or even weeks between the birth of the first and second twins was well known

years gone by, but during this century, at any rate, it has become the established practice to intervene in cases of delayed cases such as the one described have therefore become rare. Pearson in 1880, according to DeLec, found that the interval between the two births if left to Nature varied from a few minutes up to 44 days. Any search for a record, however, is unprofitable because the longer the interval the more likely is one to become involved in the old debatable problem of overfoetation and in reports of cases of doubtful authenticity. Moreover cases in which one twin has been aborted early in pregnancy, the other remaining *in utero* to continue to develop a term, would need to be considered.

The management of twin delivery is now generally agreed immediately after the birth of the first baby abdominal examination should be carried out to make sure that the lie of the second child is longitudinal and that it is alive. If after an interval of twenty to thirty minutes the uterus remains inactive, then even in the absence of maternal and foetal distress the second bag of membranes should be ruptured artificially and the presenting part pressed into the brim of the pelvis by bimanual manipulation. Expulsive uterine contractions then follow quickly. Many prefer less conservative treatment and carry out vaginal examination and rupture of the membranes (first correcting the position of the baby) immediately after the first twin is born. Some even proceed at once to deliver the second child by forceps or by breech extraction after version. If this is done, however, the delivery should not be unduly hurried.

Although all went well in the case quoted in the question, delay in the delivery of the second baby does involve risk. The baby may die *in utero* from placental separation or prolapsed cord, so far as the mother is concerned there is always a possibility of haemorrhage, while some degree of intrauterine infection is almost inevitable.

Chronic Barbiturate Intoxication

Q—*What risks are associated with continuous and high dose medication with barbiturates?*

A—A large number of symptoms and signs have been attributed to prolonged medication with barbiturates. These include vertigo, ataxia, nystagmus, tremor, motor paralyses, squint, diplopia and facial palsy. Syndromes resembling lethargic encephalitis, bulbar palsy and cerebral thrombosis have been reported. Psychic disturbances, such as increasing lethargy, mental hebetude, depressive states, mental deterioration, mania, and a condition resembling delirium tremens, have been noted. Finally, there are records of gastro intestinal irritation, albuminuria, anaemia and porphyrinuria. In spite of this wealth of possible symptoms, it is remarkable how rare instances of chronic barbiturate intoxication are. It may be as some have held, that this is because they are seldom recognized.

Those drugs whose effect is of long duration are said to cause chronic poisoning more readily. Complete recovery usually follows withdrawal of the barbiturates for two to three weeks.

Auricular Fibrillation

Q—*A woman aged 60 has suffered from auricular fibrillation for a number of years. This has been controlled by digitalis folia 1/2 to 1 gr (32 to 65 mg) administered once or twice daily as required. Recently she has shown intolerance to digitalis and the fibrillation has returned with an apex beat of 140 and signs of congestive failure. Please advise as to further treatment.*

A—In view of the fact that the patient has developed congestive failure she should be put to bed well propped up with pillows in the position of greatest comfort. Diet should be nutritious and small in bulk, with frequent feeds, and fluids should be restricted to 2 pints (1.14 litres) or even less daily provided thirst is avoided. No added salt should be given. As digitalis folia has not been well tolerated, digoxin 0.25 mg three or four times daily might be given for the rapid auricular fibrillation, the dose being decreased according to pulse rate and general response. A heart rate of approximately 70 should be aimed at but coupling avoided. Sleep is an important consideration and for this morphine gr 1/4 (16 mg.) hypodermically (or sublingually using the hydrochloride or tartrate) should be given for a few nights provided there are no respiratory

contraindications and the response is good. It may be found by trial and error that a larger dose is needed. For the bowels an enema should first be given followed by appropriate laxatives. Subsequent treatment will depend on progress and also on the precipitating causes of the failure.

If the response is good the pulse slows and the signs of congestive failure disappear. The patient should be kept in bed for about three weeks and then gradually allowed to get up and do more, the return to activity being carefully graduated according to the response to effort. Sleep should be ensured with phenobarbitone and the diet gradually increased, but all excessive consumption of food and unnecessary fluid or salt should be avoided. If the response on these lines is not satisfactory and signs of the congestive failure persist, then mercurial diuretics should be tried, each injection being preceded by ammonium chloride gr 30 (2 g) administered four hours before Mersalyl 1 ml intramuscularly might be given first, followed by 2 ml every third or fourth day so long as the injections are well tolerated and no contraindications arise. They should be continued with diminishing frequency until the oedema has completely disappeared.

Localized Slimming

Q—*What methods are effective for reducing fat locally without reducing the weight in general? In particular, how may fat be dispersed from around the hips and buttocks?*

A—It is doubtful whether any methods are effective in reducing fat locally. An electrical device used to be sold which massaged the areas mentioned, a simpler means was a roller with an irregular surface with which the patient applied violent friction where reduction was desired. Some masseurs claim that by means of vigorous—and painful—rolling, pinching, and rubbing they can disperse local deposits of fat. The theoretical basis of all these methods is claimed to be the actual disruption of fat cells. Their efficacy is doubtful but it is likely that the energy expended in wielding the roller is to the patient's benefit.

Venepuncture by Non-medical Persons

Q—*Apart from specially trained individuals as for example in V.D. clinics should venepuncture be carried out by non-medical personnel? Is it good hospital practice to allow a ward sister or senior nurse to take blood specimens for routine laboratory tests?*

A—The question of venepuncture for withdrawal of a blood sample must be considered separately from that of venepuncture for injection of a drug. It is clear that the latter operation entails risks to the patient for which a medical practitioner must be responsible. In some V.D. clinics it is deputed to a trained orderly, although this appears inadvisable. In many hospitals specimens of blood are taken by nursing staff or by laboratory technicians, this arrangement is often expedient and there seems no reason to regard it as unethical. Inexpert venepuncture can be uncomfortable for the patient, but it is seldom, if ever, harmful. The common sense answer depends on the dexterity of the performer, and many sisters and technicians possess this in high degree.

How Penicillin Acts

Q—*How long does penicillin take to act? Is the problem one of therapy continued until all invading germs have had an opportunity of contact with an immediately lethal substance or one of gradual extinction over several generations by a maintained adverse environment which has been experienced by all the bacteria from the beginning of treatment? Can an in vitro experiment yield a precise answer?*

A—*In vitro* studies enable this question to be answered as follows. When susceptible and actively growing bacteria are exposed to a lethal concentration of penicillin growth ceases after a single generation and death rapidly ensues, sterilization being almost complete within a few hours under optimal conditions. It might be concluded from this that a single dose of penicillin should be capable of terminating an acute infection. That this is not usually so is due to at least three causes. Even in an apparently uniform actively growing bacterial population there is a very small minority of cells which are not killed, and bacteria which are not actively growing are not subject to

rapid lethal action. There will thus be survivors of the initial attack which will multiply and continue the infection if treatment is not continued. Thirdly, there may be some part of the infected area not in close enough contact with the circulation for penicillin to reach it quickly and in adequate concentration. For these reasons total extermination of the invading bacteria by the action of penicillin alone is usually not to be expected, its influence must be maintained until the normal defence mechanism has been enabled to complete its work.

Prevention of Rust on Instruments

Q—Is there any substance which can be added to boiling water when sterilizing instruments which will prevent their rusting? Is it true that borax serves this purpose?

A—It is true that rusting will not occur in water containing borax in solution, even when instruments are immersed in it for weeks. This substance is therefore included in the formula of disinfectant solutions, of which the main constituent is formalin or *p*-chlorometacresol used for the storage of sterile instruments. Two such formulae are

R		
Borax	15 g	
Formalin	25 ml	
Phenol	0.4 g	
Aq. dest.	ad 100 ml	
R		
Borax	10 g	
<i>p</i> -chlorometacresol	0.2 g	
Spirit	0.6 ml	
Aq. dest.	ad 100 ml	

The addition of borax to water in which instruments are boiled is usually considered unnecessary, since there is no time for appreciable rusting to occur unless the instruments are left in the sterilizer for some time after it has cooled. On the other hand, the addition of 2% sodium carbonate has the advantage that it enables boiling to destroy all kinds of bacteria including spores which may be unaffected by boiling in plain water.

Ergot and Ergotamine Poisoning

Q—What are the early and late toxic effects of ergot and of ergotamine?

A—A comprehensive account of the toxic symptoms produced by ergot and ergotamine is given by von Storch (*J. Amer. med. Ass.* 1938, 111, 293). The usual form of ergot poisoning is the gangrenous type, in which the premonitory symptoms are general lassitude, mental dullness, vague lumbar pains, cramp-like pains in the calves and burning pains in the extremities followed by intense waves of heat and cold. The less common form is the convulsive type, usually associated with malnutrition, in which there are contractures of the muscles of the face, hands and feet.

The first signs of poisoning due to ergotamine are nausea, vomiting, numbness, or tingling of the hands or feet, and muscle pains. The later signs are gangrene of the extremities, which usually remains dry. In a small proportion of patients there may also be insomnia and restlessness, substernal oppression, and vascular pain around the femoral or brachial vessels or in varicose veins.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Practitioner's Expenses

J F inquires whether the cost of repairing a consulting room chair and of replacing a divan in his assistant's bedroom is allowable.

****** Yes—in both cases.

Cost of Assistant's "Living in" Accommodation

G L asks how much can be allowed for such expenses.

****** In addition to the salary paid the principal can deduct sums expended to provide the board and lodging which the assistant is entitled to under the service agreement. No rule can be suggested for calculating the amount except that it should be a reasonable proportion of the general cost of maintaining the private establishment plus any sums specifically expended for the assistant's benefit.

Letters and Notes

Nocturnal Diuresis

Dr B E READ (Shanghai) writes: Nocturnal diuresis among internees in Shanghai was most pronounced. There is no evidence that I know of to support the theory that this is due to a rice diet as suggested in Dr C Romer's letter (Aug 3 p 176). The Chinese on a rice diet do not micturate more freely than those in North China on a wheat diet, nor is a greater volume of urine excreted. I attribute the nocturnal diuresis observed to the nervous strain under which internees were living. My personal experience may be of interest. Living in one camp for 15 months in a dormitory of 67 men, I, in common with many of the others, was micturating five to six times a night. This entirely ceased when I moved to a second camp where at first I had a quiet private room. A month later I shared a larger room with a doctor and some time later I spent a year in a quiet billet with five other congenial people and had no recurrence of this trouble in an extreme form though the diet was the same in both camps. Internees were generally unwilling to acknowledge any nervous strain. One man, who before internment was in the hands of the Gestapo for about one month, two weeks after his release said he was much better, having micturated the previous night only fourteen times.

Swallowed Kirby Grip

Dr A P MACDONALD (Newark) writes: In view of Mr A M Desmond's communication (Dec 28, 1946, p 1012) the following case is considered worth recording. A child aged 2½ years was admitted to the Newark and District General Hospital on Dec 19, 1946, with a history of having swallowed a Kirby grip two days previously. There was also a history that the child had been operated on successfully for pyloric stenosis at the age of 7 weeks. On admission, the child did not complain and nothing abnormal was discovered clinically. X-ray examination showed the hair grip to be lying in the stomach. The patient was given stodge food and cotton-wool by mouth. Further x-ray examination on Dec 2 showed the Kirby grip still in the stomach, and a small quantity of barium was given for confirmation. The child did not complain of any symptoms and it was decided to wait a little longer. After the barium the patient vomited three times, and the following day one week after swallowing the foreign body he vomited the Kirby grip back with a small quantity of barium. The grip measured 2 in (5.1 cm) in length.

Disclaimer

Drs G F TRIPP, F N NEWNHAM, D M THOMSON, A B BAXTER, M J LINDSEY, T O MASON, G R FORD, C F KNIGHT (Dartford) write: We hereby disclaim all responsibility for recent Press reports on the medical service in Dartford, which were published without our knowledge or consent.

Correction

Dr J F BROMLEY writes: As honorary secretary of the Faculty of Radiologists, I would like to draw attention to the fact that your account in the *Journal* for Jan 4 (p 25) of the discussion on carcinoma of the stomach, there is no reference to the part played by the Faculty of Radiologists. In fact the bodies taking part in the joint meetings were the British Institute of Radiology, the Faculty of Radiologists, and the R.S.M. Section of Radiology, and the chairman at the first meeting on Dec 14 was our President, Dr C (Teall). This was clearly stated in the notice of the meetings issued by all three societies.

A misprint occurred in the report of Sir Allen Daley's speech at the luncheon of the City of London Corporation Health Committee (*Journal* Jan 4, p 24). Under the sub-heading 'Hygienist and Surgeon,' col 1, line 21, the date 1885 should read 1855.

RETRODISPLACED GRAVID UTERUS

BY

H H FOURACRE BARNES, F.R.C.S., M.R.C.O.G.

First Assistant Obstetric Unit, University College Hospital

Extensive studies have shown that approximately 20% of nulliparous women have retrodisplaced uteri. Polak (1926) in an analysis of 2,000 cases found 18% of congenital retroversions in nulliparous women and 35% in post-partum women. Since 1928, 66 patients with retrodisplaced gravid uteri have been admitted to the wards of University College Hospital. They were admitted on account of threatened abortion, hyperemesis gravidarum, incarceration of the uterus, or because it was considered necessary to keep the patient under observation. It should be pointed out that many cases are seen and treated as out-patients. In addition it is hardly necessary to point out that a number of pregnant women who present themselves at the clinic with normally anteverted uteri after the 16th week of pregnancy may have started the pregnancy with a retrodisplaced uterus. According to the figures of Polak (1926) 18% of primigravidae and 35% of multiparae should have a retrodisplaced gravid uterus in the early weeks of pregnancy. This, however, would only be so if the woman with the displaced uterus were fertile.

During the years 1944-5 474 patients were examined in the antenatal department of this hospital before or during the 12th week of pregnancy, 381 were primigravidae, of whom 21 had a retrodisplaced uterus, and 93 were multiparae, of whom 6 had this malposition of the uterus. The incidence of the retrodisplacement from this small number of cases is therefore 5.5% for primigravidae and 6.5% for multiparae. Hence the incidence of the condition is perhaps greater than is generally realized and certainly much greater than that obtained from the records of patients admitted to the wards. Similarly, since those not admitted usually continue their pregnancies to a successful conclusion, the incidence of abortion obtained from in-patient records is greater than it is in fact.

Sterility

It is generally supposed that retrodisplacement may be a cause of sterility. Wilfred Shaw (1945a) states "It is common clinical experience that sterility can be cured by suspending the uterus in a position of ante flexion by operation so that it is reasonable to assume that the retroflexion of itself may cause sterility." Beckwith Whitehouse (1935) makes a similar statement "Women with a backward displacement are by no means necessarily sterile, but it has been frequently observed that after several years of non-fertile marriage cure of a backward displacement has been followed by conception. This displacement is therefore a possible factor in the causation of sterility." Ten Teachers

(1942a) state "Retroversion of the uterus either may be congenital or may occur for the first time after abortion or childbirth. That the majority of women can become pregnant with the uterus in this position is undoubtedly the case. In a small proportion, however, the retroversion would appear to be a definite cause of the inability to conceive in that pregnancy has at once followed the replacement of the organ." Fairbairn (1924a) says "Possibly they [conical cervix, pin-hole os, and retroversion] may play a part in lessening the chances of conception, but pregnancy occurs so often in spite of them that it cannot be a big part."

Among the in-patient cases under review there were 33 primigravidae. The duration of marriage before conception is known in 25 of them and two others were unmarried. Seven of the 25 married primigravidae had been married for more than 4 years, and three of these had previously presented themselves to a gynaecological clinic on account of sterility of 4 years', 7 years', and 7 years' duration. The three patients were investigated in the usual way, and each had either an insufflation or hysterosalpingography. Two conceived immediately and the third within a month of this investigation.

It seems reasonable to suggest, therefore, that any woman complaining of sterility in whom the only abnormality to be found is a retrodisplaced uterus should be investigated and treated along the same lines as would be a woman with an anteverted uterus. This investigation should include, of course, the determination of tubal patency and fertility of the husband. Only if conception has not taken place within a reasonable number of months after such investigations and treatment should operative correction of the malposition be considered in a nullipara, or manual correction and pessary treatment in the multipara if this is possible.

Abortion

Sinclair (1900), writing on the retrodisplaced gravid uterus, states "It is, in my opinion, probably the most common cause of repeated abortions in the same woman." Barnett (1941) states "Abortion is a frequent termination of the retroflexed pregnant uterus, usually occurring after about two and a half months of pregnancy, and is caused by a disturbance in the uterine circulation." Other authorities (Munro Kerr, 1937a, Wilfred Shaw, 1945a) write in the same vein.

In the present series of admitted patients there were 14 abortions out of a total of 44 pregnancies which were under observation until the termination of the pregnancy. There were a further 22 patients who were discharged from

hospital undelivered with an anteverted gravid uterus (see Table I) The ratio of abortions to pregnancies is therefore,

TABLE I—*Outcome of Pregnancy*

	Abortion	Live Child	Discharged Undelivered	Totals
Primigravidae				
(a) Before onset of symptoms of incarceration	8	17	5	30
(b) After onset of symptoms of incarceration	0	1	2	3
Multiparae				
(a) Before onset of symptoms of incarceration	5	10	11	26
(b) After onset of symptoms of incarceration	1	2	4	7
Totals	14	30	22	66

at worst, 1/3, for it is probable that, of the 22 cases, the abortions would have been readmitted, whereas the successful pregnancies might have been delivered elsewhere. Furthermore, when one considers the number of women with a retrodisplaced pregnant uterus which spontaneously anteverts while they are under observation and treatment as out-patients and who continue their pregnancies successfully, and also the number of patients who begin pregnancy with a retrodisplaced uterus but who cannot be diagnosed owing to late presentation at the clinic, it is clear that the incidence obtained must be greater than it actually is. Danforth and Galloway (1926) studied a series of 55 private patients with a retrodisplaced pregnant uterus, and found the incidence of abortion to be as low as 1 in 13.7 pregnancies. Of the 27 women with a retrodisplaced gravid uterus examined before or during the 12th week of pregnancy in the years 1944-5, only 2 aborted—an incidence of 1 in 13.5 pregnancies. Of the 447 women with an anteverted gravid uterus examined before or during the 12th week of pregnancy during the same period, 54 aborted—an incidence of 1 in 8.3.

The usual quoted incidence of abortion for all pregnancies is 1 in 5 (Malins, 1903, Wiehl, 1938), and Adair (quoted by Danforth and Galloway, 1926) states that 1 in 3+ is nearer the truth.

More detailed study of the abortions in the cases admitted to University College Hospital shows that 8 occurred in primigravidae and 5 in multiparae. There was one other abortion in a multipara with a retrodisplaced incarcerated gravid uterus. The earliest abortion occurred at 9 weeks and the latest at 25 weeks. Six of the abortions came from uteri after anteversion, six from uteri while still retrodisplaced, in another the position of the uterus is not stated and the 14th was from the incarcerated uterus. The abortions from the anteverted uteri took place 2 days, 5 days, 14 days, 7 weeks, 11½ weeks, and 15 weeks after anteversion had been attained. It would appear that the retrodisplaced gravid uterus which is destined to abort does so in spite of attaining a position of anteversion and even after maintaining the pregnancy in the new position for some weeks.

Table II outlines the treatment adopted for the patients before the onset of symptoms of incarceration. From it

TABLE II—*Outcome of Pregnancy in Cases Before Onset of Symptoms of Incarceration*

Treatment	Abortion	Live Child	Discharged Undelivered	Totals
Postural	6	12	6	24
Pessary alone	3	0	3	6
Manipulation with or without pessary	4	15	7	26
Totals	13	27	16	56

we see that the treatment adopted has little effect on the outcome in this small series of patients. In spite of manipu-

lation 15 patients continued their pregnancies successfully. It was noted, too, that after such a procedure the uterus aborted some weeks later, when one would consider any disturbances from manipulations to have ceased. It would be idle to suggest, however, that manipulation might not materially affect the outcome if signs of threatened abortion immediately preceded it or if it were carried out too forcibly.

From the above observations it would appear that the incidence of abortion in patients with retrodisplaced gravid uteri is at least no higher than that for all pregnancies, that the abortion can occur some weeks after anteversion has been attained and that the treatment adopted seems to have little effect on the outcome. The importance of the retrodisplacement of the uterus as a cause of abortion has been overemphasized. This was certainly borne out by experience in the Services, where there was opportunity for seeing many early pregnancies. It is therefore suggested that the position of the uterus is likely to be a factor in abortion only where it causes incarceration in the bony pelvis. Even then the pregnancy often continues at the expense of the bladder. Gibberd (1938a) says "A retroverted uterus is frequently blamed for an abortion, but except when it leads to incarceration at the twelfth week it is difficult to understand why the retroversion *per se* should affect the safe embedding of the ovum. Indeed, it is doubtful whether retroversion is to be regarded seriously from this point of view." Eden and Holland (1937) state "Retroflexion of the uterus, apart from rare cases of incarceration of the pregnant uterus, is seldom a cause of abortion, and when the two are associated and other causes can be excluded it is probable that it is not the displacement but some concomitant abnormality of the endometrium that is to blame." Treatment of the retrodisplaced pregnant uterus should therefore be primarily instituted to prevent incarceration.

The question is of some moment, for many authorities advocate operative correction of the retrodisplacement following an abortion considered to be due to the malposition (Munro Kerr, 1937b, Browne, 1946a, Ten Teachers 1942b, Wilfred Shaw, 1945b). In a number of cases this has been rewarded by success. On the other hand it has been unsuccessful, and in spite of the anteverted position abortion has been repeated. In this connexion three of the multiparous patients are of interest.

Patient No. 39 had a ventrosuspension operation in 1940. In 1941 she had a six-weeks abortion and in 1942 a 10 weeks abortion. In 1943 she was seen when 13 weeks pregnant with a retrodisplaced uterus. The uterus was manually replaced and a ring pessary inserted. The pregnancy continued and she was delivered of a live infant at term. If the ventrosuspension operation was successful in anteverting the uterus, then the abortion in 1941, and probably the one in 1942, occurred in spite of the correction, and retrodisplacement took place after the second unsuccessful pregnancy. If ventrosuspension was unsuccessful in anteverting the uterus then all three pregnancies occurred in a retrodisplaced uterus and the third was successful.

Another patient (Case 42) had a retrodisplaced gravid uterus in 1936. She was seen when nearly 12 weeks pregnant, was treated by pessary, and spontaneous anteversion occurred. The pregnancy continued until 23 weeks, when she aborted. In 1937 she was seen when 9 weeks pregnant with retrodisplaced uterus. Manual replacement and pessary treatment was given and the pregnancy continued to a successful conclusion. Had she been operated upon for the malposition between the two pregnancies the operation would have been credited with the success.

Patient No 43 aborted at 20 weeks early in 1929, at 8 weeks late in 1929, at 16 weeks in 1930, and at 20 weeks in 1932. In 1933 she was seen when 10 weeks pregnant with retrodisplaced uterus. Manual replacement and pessary treatment was given. She aborted at 25 weeks. She was next seen in 1934 when 7 weeks pregnant with retrodisplaced uterus. Manual replacement and pessary treatment was again given. The pregnancy was continued and she was delivered of a live premature infant. The uterus was in an anteverted position when seen three months after delivery. In 1936 she was again seen when 12 weeks pregnant with an anteverted uterus. This ended in premature delivery at 29 weeks and neonatal death of the infant. The patient was again seen in 1939. She was 12 weeks pregnant with an anteverted uterus. The pregnancy terminated in abortion at 27 weeks. This appears to be a case of habitual abortion (the pregnancy surviving long enough to end in premature delivery on two occasions) which was influenced by the position of the uterus.

Operative correction of a retrodisplaced uterus on account of abortion is therefore not advocated. The next pregnancy should be under observation as soon after the first missed period as possible and the patient treated as a case of habitual abortion. The position of the uterus is treated along the lines to be mentioned later only to prevent incarceration.

Incarceration of the Retrodisplaced Pregnant Uterus

Incarceration of the retrodisplaced pregnant uterus occurred in ten patients—3 primigravidae and 7 multiparae. Sudden onset of retention of urine accompanied by lower abdominal pain was the cardinal symptom. This was occasionally preceded by a few days of painful, difficult and frequent micturition. Sinclair states that frequency of micturition precedes the onset of retention. One patient had retention with overflow, the paradoxical incontinence starting three days after the onset of the retention. The onset of the symptoms will depend on the relative size of the growing uterus to the mother's pelvis. In the present series it occurred as early as the 13th week of pregnancy and as late as the 17th week.

Sacculation of the incarcerated uterus is uncommon. Fairbairn (1924b) states "A rare occurrence described in the books, of which, however, I have neither any personal experience nor met anyone who has is sacculation. One case was diagnosed as sacculation of the retrodisplaced gravid uterus. This patient was seen when 17 weeks pregnant. She complained of lower abdominal pain and vomiting of 3 weeks duration. There was no retention of urine. The diagnosis was made on palpation of the fundus of the uterus in the pouch of Douglas and per abdomen, a uterine tumour reaching half-way to the umbilicus. She was kept under observation and at the 19th week aborted.

Another patient a multipara (not included in the above series owing to late presentation), was seen at University College Hospital when 27 weeks pregnant. She was found to have a sacculated retrodisplaced uterus, the cervix of which was displaced upwards above the level of the symphysis pubis. There was no history of urinary symptoms. She was admitted in labour when 32 weeks pregnant. The fundus of the uterus in the pouch of Douglas contained the foetal head. Caesarean section was performed and the diagnosis of sacculation definitely confirmed. The anterior wall was only 1.8 in (32 mm) thick, and before closing the abdomen the position of the uterus was corrected manually. In 1937 this patient again became pregnant and again had a sacculated retrodisplaced uterus. She went into premature labour at 30 weeks and was treated at

St Pancras Hospital. There it was found possible to push up the fundus of the uterus out of the pelvis, the cervix descending to its normal position, and she was delivered *per vias naturales* of a stillborn premature infant.

The cause of the retention of urine is imperfectly understood. Gibberd (1938b) and the Ten Teachers (1942c) state that with the elongation of the urethra there is an upset of the neuromuscular mechanism of micturition. Browne (1946b) says that it is due to pressure on the neck of the bladder combined with the elongation and narrowing of the urethra. Reed (1904) regards the retention as a form of "pressure paralysis" due to interference with the nerves supplying the bladder.

The urethra is elongated and narrowed as the bladder rises out of the pelvis and the enlarging uterus fills the pelvic cavity. A similar state of affairs exists during the second stage of labour, when the bladder becomes an abdominal organ and the foetal head is passing through the lower part of the pelvic cavity. In the cases of sacculation mentioned there was no retention of urine although the urethra must have been lengthened. In another patient there was lower abdominal pain preceding difficult micturition at the 16th week, but the onset of retention was prevented by prompt treatment. Again the urethra must have been lengthened. In spite of lengthening of the urethra in these three cases, retention did not occur as might be expected if mere lengthening of the urethra caused an upset of the neuromuscular mechanism of micturition. It seems reasonable to suggest that the retention of urine is mechanical in origin. As compared with the normal urethra, the elongated and narrowed urethra is less able to withstand the external occluding pressure of a pelvic tumour such as the incarcerated uterus or the foetal head. The occluding pressure need not be great and may allow the introduction of a rubber catheter. The picture visualized is akin to a stretched rubber tube where pressure to occlude its lumen is less than would be needed if it were unstretched.

Pregnancy as a Cure of the Retrodisplacement

Of the 33 primigravidae 16 were followed throughout pregnancy to a successful conclusion and seen in the post-natal period. Nine of these 16 patients had an anteverted involuted uterus at 8 weeks post partum. Four of these were seen some months after delivery, when the anteverted position was found to be still present. The anteverted position in these nine patients was obtained solely by postural treatment in the puerperium. One may therefore expect pregnancy to cure more than half the cases of congenital retrodisplacement of the uterus. Whether a woman who starts a pregnancy with a congenitally retrodisplaced uterus and who finally, after a successfully concluded pregnancy, is left with an anteverted uterus can be regarded as "cured," or whether such a state of affairs is desirable, are moot points. Certainly the anteverted uterus with its fundus above the level of the cervix, in a woman in the standing, sitting, or normal lying posture is mechanically in a better position for drainage of its cavity than a retrodisplaced one where the fundus is possibly at a lower level than the cervix. Certain it is, too, that the anteverted position avoids the possibility of incarceration in a subsequent pregnancy.

Treatment of the Retrodisplaced Gravid Uterus

The importance of the retrodisplaced gravid uterus lies in the possibility of its becoming incarcerated. This may occur as early as the 13th week of pregnancy and may be preceded by a few days of difficult, painful, and frequent micturition. No active treatment is really needed, therefore until the 12th week of pregnancy, but passive postural treatment should be adopted before this time. Many cases

spontaneously antevert in the early weeks with or without the aid of posture. When seen in the early weeks patients should be instructed to sleep in Sims's position or, if they prefer, in the full prone position. If anteversion has not occurred by the 12th week, then more active measures should be adopted to avoid the possibility of incarceration with its accompanying pain, retention, and possible super-added urinary infection. Preferably, the patient should be admitted to hospital, a large rubber watch-spring pessary inserted into the vagina, as advocated by Sinclair (1900), and posture continued under supervision. The postural treatment may be elaborated to include knee-chest position and prone lying for short periods during the day, and instructions should be given that any difficulty in micturition is to be promptly reported. Such difficulty may be due to too large a pessary, and a full bladder will tend to prevent anteversion. The regime should be tried for a few days and, if unsuccessful, manual reposition without or with an anaesthetic should be attempted. Once the uterus is anteverted, a watch-spring pessary is inserted to help retain the anteverted position and is worn until the fundus approaches the umbilicus at about the 20th week.

There will be very few cases where one or other of the above procedures is unsuccessful. Laparotomy is mentioned by many authorities for such cases, dense adhesions being blamed for failure of the more conservative methods of treatment. There was one case in the series under review in which the patient had a right tubal pregnancy treated by operation in 1928. In 1929 she was diagnosed as having a fixed retroversion. She was next seen in 1932, when 8 weeks pregnant with a retrodisplaced uterus which appeared fixed. She was treated by posture. Spontaneous anteversion occurred and the pregnancy continued to a successful conclusion. It seems probable that there were adhesions, which did not, however, prevent anteversion occurring as pregnancy advanced. On the other hand, if adhesions are extensive it is probable that the patient will be sterile.

If incarceration occurs then it is the bladder that must receive attention in the first instance. Continuous catheterization is preferable to intermittent catheterization, and should be given along with postural treatment. Slow decompression of the bladder is needed if the retention has been of long standing. If this treatment is unsuccessful in 24 to 48 hours, a watch-spring pessary is used for 48 hours as outlined above. If such procedures fail manual reposition will be needed. Urinary antiseptics should be given in all cases.

Summary

A series of 66 patients with a retrodisplaced gravid uterus, who were admitted to the wards, is analysed.

A plea is made for conservative treatment of the sterile woman with a retrodisplaced uterus.

It is suggested that operative correction of a retrodisplaced uterus for a previous abortion is unwarranted.

Incarceration may occur between the 13th and 17th weeks of pregnancy, and two cases of sacculation of the incarcerated gravid uterus are briefly described. The cardinal symptom of incarceration is sudden onset of retention of urine with lower abdominal pain.

Treatment of the condition which is primarily instituted to avoid incarceration, is outlined.

I wish to express my gratitude to my late chief, Prof F J Browne, and to Prof W C W Nixon for permission to make use of the case records of the Obstetric Unit, University College Hospital.

LIVER DAMAGE IN AMOEBIASIS

BY

DENNIS SHUTE, M.D., D.T.M.

Despite the obviously close connexion of amoebic colitis with liver disease there have been surprisingly few attempts to investigate the condition of the liver in amoebiasis other than by clinical methods. Much of the symptomatology of amoebic dysentery suggests that there is some degree of liver damage, the toxic appearance, anorexia, emaciation, sallow complexion, and chronic ill-health are such symptoms and signs, and to cases presenting these Manson-Bähr (1943) has applied the term "amoebic cachexia". In addition, he says (Manson-Bähr, 1940) that during the course of an attack of amoebic dysentery, and for many months afterwards, the possible supervision of amoebic hepatitis must be borne in mind, and the "condition of the liver must receive the most careful attention", but this careful attention is presumably dependent entirely upon the clinical acumen of the physician.

The *Quarterly Cumulative Index Medicus* for the years 1931 to 1944 and the *Tropical Diseases Bulletin* from 1934 to 1944 list only four attempts to apply laboratory methods to assessments of liver damage in amoebiasis—namely Heilig and Visveswar (1944), Gminder (1939), Barhagallo (1936), and Cordaro (1938). In the case of the first three investigations the tests were the hippuric acid synthesis, the Takata-Ara and the Weltmann coagulation reaction. The paper by Cordaro was not available.

When an investigation of the condition of the liver in amoebiasis was contemplated consideration had to be given to the limited time, equipment, and technical assistance available in the laboratory of a large naval auxiliary hospital, and a method chosen which it was hoped, not only would give reliable results but could also be applied rapidly to a reasonable number of cases. Consideration of the liver-function tests and those empirical procedures which are stated to assess the degree of liver parenchyma damage led to the choice of Hanger's cephalin-cholesterol flocculation test (CCFT) as the most promising to apply to this problem.

The CCFT was first introduced by Hanger in 1938, and since that time has been studied and used considerably in North America and, to a smaller extent, in Britain. The results and conclusions have been published by Hanger (1939), Pohle and Stewart (1941), Hanger and Patek (1941), Gutman and Hanger (1941), Rosenberg (1941), Lippman and Bakst (1942), Mateer, Baltz, Marion and MacMillan (1943), Mirsky and von Brecht (1943), Bruger (1943), Kirschner and Glickman (1943), Kopp and Solomon (1943),

Yardumian and Weisband (1943), and Dick (1945) The consensus of opinion is that it is a sensitive means of demonstrating disease of the liver parenchyma cells

Material, Technical Procedure, and Results

The patients were selected in that they were all Europeans Asiatics (Ceylonese) were excluded in view of the high incidence of chronic malaria and helminth infestations to be found in them This was of considerable importance, as the sera of malaria patients will cause flocculation with cephalin-cholesterol emulsions (Kopp and Solomon, 1943), while Karunaratne (1940) reported five cases of histologically perfect hepatic cirrhosis in Asiatic children with heavy hookworm infestations Chopra has estimated that 90% of the natives of Ceylon harbour the *Ankylostoma duodenale*, whereas among the European Service personnel dealt with over a period of a year (during which time 450 faecal specimens were examined monthly) only one case of hookworm disease was diagnosed

The diagnosis of amoebiasis was established in every case by the demonstration of the trophozoites or the cysts of *Entamoeba histolytica* in the faeces or in the material obtained by sigmoidoscopy or proctoscopy

The CCFT was done on each patient's serum as soon as the diagnosis was made, approximately half-way through the course of anti amoebic treatment, and on completion of the course As the treatment for amoebiasis is both exhausting and unpleasant, the patients were always granted fourteen days' sick leave, which they usually spent in a hill station Thereafter they returned to the hospital for the test of cure This necessitated a stay of about a week in hospital so the opportunity was taken to carry out a final CCFT before discharge to duty Owing to the exigencies of the Service, this final test had to be omitted in some cases

The scheme of treatment in all cases was based on that advised at the Liverpool School of Tropical Medicine, and is as follows

Emetine hydrochloride was given subcutaneously at night in 1-gr doses to a maximum of 10 gr Many of the patients had less than the maximum dosage, as the sterilizing course was started as soon as the acute symptoms had been controlled

The sterilizing course lasted 21 days the days being numbered 1 2 3 4 etc, to 21 Day 1 is the day following the last emetine injection

Odd Days 7 a.m. 11 a.m., 3 p.m. and 7 p.m. 1 gr (65 mg) of auremetine in a capsule 9 a.m. 1 p.m. and 5 p.m., 1 dr (4 g) bismuth subnitrate by mouth in a quarter-pint (142 ml) of milk

Even Days 7 a.m. 12 noon and 5 p.m. 4 gr (0.25 g) of stovarsol by mouth 8 a.m. 2% sodium bicarbonate lower bowel wash out, 9 a.m. 2-4% quinine retention enema of 1 pint (568 ml) to be retained 8-10 hours

Sick leave was spent in a hill station

The test of cure was 7 days in hospital for faeces examination and in some cases sigmoidoscopy

Heiliger's test was done (1) before the first dose of emetine hydrochloride (2) between day 9 and day 11 of the sterilizing course (3) within two days of the completion of the sterilizing course and (4) on return from sick leave for the test of cure

The cases were divided on clinical grounds into four groups as follows (1) acute amoebic dysentery (2) chronic amoebic colitis (3) amoebiasis presenting with unusual symptoms (4) amoebic hepatitis

Although this work was intended primarily as an investigation of the liver in cases of intestinal amoebiasis, the opportunity was taken of applying the CCFT to a small number of patients suffering from amoebic hepatitis They were selected with considerable care so there was no reasonable doubt of the correctness of the diagnosis It is

well known that *E. histolytica* is frequently not found in the faeces of patients with amoebic hepatic disease (55% according to Manson-Bahr, 1940), but in all the cases shown in Table IV the cysts of *E. histolytica* were demonstrated and this fact, combined with the symptoms, physical signs radiological evidence, and white blood cell counts, made the diagnosis almost certain The response to emetine therapy clinched the diagnosis in every case

Cephalin was extracted from sheep brain and made up with cholesterol in ether, as originally described by Hanger (1939) His technique for the test was also followed, except that the final readings for the degree of flocculation (i.e. those shown in Tables I-IV) were made after a 24-hour interval and not after 48 hours Dick (1945) states that a considerable proportion of normal sera will cause some flocculation after 48 hours, and this observation was amply confirmed in the present work

Normal controls were included as a routine with every batch of sera from amoebiasis cases which were put up for the CCFT The numbers in the batches varied from 10 to 26, and with each batch at least two normals and one abnormal were included The normal controls were sera from members of the medical, nursing, and sick-berth staffs of the hospital Results were as follows

Total No. tested	47
No. with negative CCFT	45 (95.7%)
positive	2

The two positives were obtained with the sera of male laboratory technicians one gave a history of severe and frequent attacks of migraine, while the other had had attacks of catarrhal jaundice 5, 21, and 31 months before the first CCFT The results of the test in these two men varied from \pm to $++$ over a period of about a year The positive control sera were obtained from cases of malaria and from patients suffering from obvious liver disease chiefly catarrhal jaundice Among the jaundice cases the results varied from $++$ to $++++$, depending upon the severity and stage of the disease Of 17 cases of malaria 8 were benign tertian and 9 malignant tertian All gave $++++$ reactions with the exception of two of the benign and one of the malignant tertian which gave only $+++$ degree of flocculation

Discussion

Heilig and Visveswar (1944) investigated the functional efficiency of the liver in 15 cases of acute or subacute amoebic dysentery using the hippuric acid synthesis test (oral technique) They concluded that over 46% had definite impairment of liver function If the cases shown in Tables I and II are considered together, approximately 49% of the patients gave evidence of parenchymal liver damage There is thus fair agreement in the results obtained, using entirely different laboratory techniques With regard to the response to treatment, it is impossible to draw an exact parallel between the work of the above named authors and that recorded in this paper, as the patients investigated with the aid of the CCFT were given the minimum quantity of emetine hydrochloride required to control any acute symptoms, followed by a complicated schedule with a multiplicity of drugs On the other hand all of Heilig and Visveswar's patients received a routine course of 12 gr (0.8 g) of emetine

Gminder (1939) applied the Takata-Ara test to the sera of 23 patients with amoebic dysentery (9 acute and 14 chronic) He concluded that there was no evidence of liver damage in any of the acute cases, while in 10 (over 71%) of the chronic cases there was some evidence of parenchymatous liver change Barbagallo (1936) used the Weltmann coagulation test in connexion with a series of patients suffering from amoebic and non-amoebic colitis

and found an increase of the coagulation band in all cases. The last two authors' results therefore do not agree with those of Heilig and Visveswar or with those obtained by using the CCFT.

With regard to amoebic hepatitis, Heilig and Visveswar found that in 11 cases there was little evidence of impairment of function, whereas in all the 5 cases shown in Table IV the CCFT was positive. The literature gives conflicting reports on the value of liver-function tests in amoebic hepatitis. Hurst (1941) maintained that the laevulose-tolerance test always demonstrated 'hepatic deficiency in this condition, but Manson-Bahr (1940) and Strong (1942) both state that liver-function tests are disappointing. Brown and Hodgson (1938), using the bromsulphthalein retention test, found a reduction of the excretion of the dye in 8 of 13 cases of amoebic liver abscess.

In view of these conflicting reports and opinions it is impossible to draw any final conclusion on the value of any type of liver test in amoebic hepatic disease. It seems probable that any liver disease demonstrable in cases of intestinal amoebiasis is due primarily to secondary bacterial invaders and their toxins. This view is strengthened by the work of Hargreaves (1944-5) and Willmore (1944-5). They found that in chronic relapsing cases of amoebic dysentery, when repeated courses of anti-amoebic treatment had failed, an initial attack on the bacteria with penicillin and sulphasuxidine often led to dramatic symptomatic improvement. Hargreaves (1945) also points out that among the bacteria normally present in the bowel lumen are numerous penicillin-sensitive strains of staphylococci and streptococci, and that there is no evidence that either penicillin or sulphasuxidine is amoebicidal.

Consideration must now be given to the morbid histological picture to be expected in the liver in the absence

of frank abscess formation. Bartlett (1916-17), while investigating the dysentery epidemic among the Allied European troops in Gallipoli in 1915, conducted necropsies on the bodies of 30 individuals. Three may be excluded here, as liver abscesses were found. In the remaining 27 the following histological features were demonstrated in the livers: (1) Degenerative changes—i.e., cloudy swelling with a little fatty degeneration of the parenchyma of the central zones of the lobules, (2) necrotic areas infiltrated with a few neutrophil leucocytes, and (3) infiltration of the portal tracts associated with degenerative or necrotic lesions. Of these 27 cases, 17 were of amoebic aetiology and 10 had suffered from bacillary dysentery. In the amoebic cases the liver showed necrosis and portal infiltration in 2, degeneration and portal infiltration in 4, degenerative changes in 9, atrophy in 1, and normality in 1. The livers of the bacillary dysentery cases had necrosis and portal infiltration in 3, degenerative changes and portal infiltration in 5, and degenerative changes only in 2. The similarity of the microscopical picture in the liver in the two diseases is obvious, and this would appear to be additional evidence of the major part played by bacteria in damaging the liver in amoebiasis.

Bartlett's findings accord reasonably well with those of Palmer (1938), who conducted post-mortem examinations on the bodies of 19 patients in whose large bowels active amoebic lesions were demonstrated. Macroscopically the liver was larger than normal in 12 cases, normal in size and weight in 4, smaller than normal in 2, while in the nineteenth case no record was kept. Microscopically, 18 cases had increased portal connective tissue ranging from marked diffuse to moderate irregular or spotty increase. In 9 of the livers there was pronounced fibrosis and definite bile-duct proliferation, and in 9 there were fatty changes. Palmer's final conclusions were that there is "definite hepatitis associated with active amoebic lesions of the colon, and this is indicated by the generalized increase of portal connective tissue, by lymphocytic and mononuclear

infiltration, and by constant degenerative changes—for example, parenchymatous degeneration, fatty changes, hemosiderosis, and hepatic cell lysis”

Summary and Conclusions

In a series of 73 cases of amoebiasis (excluding those proved to have hepatic involvement) 37 (50.6%) gave evidence of damage to the liver parenchyma—that is, ++, +++, or ++++ flocculation in Hanger's CCFT. The cases were divided on clinical grounds into three groups (1) acute amoebic dysentery (2) chronic amoebic colitis, and (3) amoebiasis presenting with unusual symptoms.

The 37 cases giving evidence of liver parenchyma damage were fairly evenly distributed among the three groups and there was no great difference in the incidence of liver involvement between the groups.

The symptomatology and physical signs did not give any indication of the cases in which hepatic damage could be anticipated.

The institution of suitable anti amoebic therapy produced a rapid recovery of the liver (as indicated by the CCFT).

A very small series of hepatic amoebiasis was investigated, but it was not considered justifiable to attempt to draw any conclusions from the results obtained.

The actual pathological changes present in the liver which can be assessed by the CCFT are probably generalized increase of portal connective tissue lymphocytic infiltration and degenerative changes—for example, parenchymatous degeneration, fatty changes, and hepatic cell lysis.

Case No.	Age	Symptoms and Physical Signs	C.C.F.T			
			1	2	3	4
1	20	Right sided thoracic pain. No history of diarrhoea. Deficient air entry at right lung base. Liver not palpable. Irregular fever to 101° F (38.3° C). Leucocytosis to 11 600/c mm. Radiograph showed right dome of diaphragm fixed and raised.	++	-	-	±
2	26	Admitted with diagnosis of clinical malaria. No history of diarrhoea. Fever to 103.2° F (39.55° C) with rigors and sweats. Liver palpable 2 in (5 cm) below right costal margin. Leucocytosis to 13 400/c mm. Radiograph showed no abnormality.	+++	-	±	-
3	24	Admitted with vomiting and right hypochondriac pain. Bout of diarrhoea 4 weeks before. Liver palpable 1 in (2.5 cm) below right costal margin. Leucocytosis to 9 900/c mm. Low fever to 99-100° F (37.2-37.8° C). Radiograph showed right cupola of diaphragm fixed and raised.	++++	++	-	-
4	20	Malaria. Shivering sweating anorexia and abdominal discomfort. Fever to 103° F (39.4° C). Liver palpable 1 in (1.25 cm) below right costal margin. Leucocytosis absent. Radiograph showed partial collapse of base of right lung.	+	±	±	-
5	37	10 days diarrhoea and pain in right chest. Tender in right hypochondrium. Liver palpable 1½ in (3.75 cm) below right costal margin. Fever to 102.4° F (39.1° C). Leucocytosis to 19 800/c mm. Radiograph showed right cupola of diaphragm fixed. Possibly an element of alcoholic cirrhosis.	++++	++++	++++	++

It is suggested that secondary bacterial invaders and their toxins are primarily responsible for these changes in the liver in cases of amoebiasis.

SPINAL WASH-OUTS IN THE TREATMENT OF PURULENT MENINGITIS

BY

J A NISSIM, MB, BS

The special physiological and anatomical peculiarities of the central nervous system constitute great impediments in the way of maximal action of penicillin in purulent meningitis. In the first place there is a blood-CSF barrier to penicillin penetration. In spite of some favourable reports on the exclusive use of systemic penicillin, increasing experience shows that even in large doses it is not reliable enough for intrathecal administration to be dispensed with. In the present series, doses of 200,000 units intravenously in adults produced no detectable penicillin in the CSF within two hours nor did 200,000 units intramuscularly to a child aged 2 years. Further evidence on this point is given by the work of McAdam *et al* (1945), Smith, Duthie, and Cairns (1946), and Kinsman and d'Alonzo (1946). Schwemlein *et al* (1946) showed that an intravenous infusion of 25 million units of penicillin in 24 hours given in the treatment of syphilis produced only 0.04–0.55 unit per ml in the CSF. So much for the efficacy of this barrier. Secondly, as the CSF becomes purulent the pia and arachnoid tend to adhere. Apart from the liability of these adhesions to produce hydrocephalus, if CSF pathways are blocked they produce cesspools beyond them inaccessible to intrathecal penicillin. Thirdly, the thick plaques of adhesions themselves form areas resistant to penicillin penetration and become admirable niduses where organisms thrive unperturbed, and, what is more, they lead to thromboses of adjoining veins with extending focal lesions and consequent fatal termination.

Experience with the present series gradually gave an impression of the overriding importance not only of the second but of the third factor in the majority of the fatal cases. Of over 40 patients observed or treated personally, the five that died directly from the meningitis and came to necropsy all showed thick, creamy, and sometimes almost organized adhesive exudates. Pneumococcal, streptococcal, staphylococcal, and influenzal varieties are included.

Contrary to expectation, only one of these five cases showed evidence of a block that would interfere with the free flow of penicillin and could be blamed for progressive meningitis beyond. Thick intensive exudate of pus at the base of the brain matted everything together, with resultant non-communicating hydrocephalus. In the four remaining cases no such blocks were found, but fibro purulent exudates formed scattered and sometimes confluent plaques, covering large areas of the brain surface and sometimes of the spinal cord.

Spinal Wash-outs

Thus it was in the post-mortem room that the idea of combating the formation of these plastic exudates by further means first arose. Some cases pass the precipitation stage before coming under medical care, but others undergo that stage immediately after. The use of spinal wash-outs was considered and its possibilities were explored.

Only the cases treated after the adoption of spinal wash-outs are included here. They number eight, and have a miscellaneous pathology (Table I). The ages ranged from 13 months to 39 years. The series comprises one case of pneumococcal meningitis, two influenzal, one staphylococcal, one streptococcal, one aseptic following rupture of an old sterile brain abscess, and two cases the pathogenic organisms of which were not isolated. All were treated

TABLE I—Analysis of Cases

Case No	Age and Sex	Organism	First seen after Onset	Result	Re-lapses	Focus	No of Wash outs
1	3 M	?	24 hrs	Recovered	0	7	1
2	2 M	<i>H strept</i>	7 days		1	Ears	1
3	29 F	<i>Staph aureus</i>	48 hrs	Died	0	Empyema	4
4	1 1/12 M	<i>H Influenzae</i>	48 hrs		1	?	0
5	39 M	?	7 days	Recovered	0	?	3
6	8 M	Pneumococcal	About 7 days	Died	0	?	4
7	1 2/12 M	<i>H Influenzae</i>	?	Recovered	1	?	13
8	20 M	Aseptic (ruptured abscess)	Same day		1	Old brain abscess	3

with sulphamezathine, 15,000 units of intramuscular penicillin three-hourly, and varying doses of intrathecal penicillin. They were first seen 1 to 7 days from the onset. Five recovered and three died. Of these three, one died of other causes, and necropsy showed no meningitis; one died because the infecting haemophilus acquired penicillin resistance, and the third (pneumococcal), admitted in coma and with hemiplegia, showed thick exudates on both hemispheres. The existence of the hemiplegia prior to admission constitutes evidence of the antecedent formation of the plastic exudate, and hence the expected lack of response.

Technique of Spinal Wash-outs

The two-needle method was rejected as ineffective except for the space between the needles, but the washing effect through one needle was considered worth investigating. On consulting the available literature later, no specific mention was found of the one-needle method of spinal lavage.

The following were fitted in series—a vacoliter of Hartmann's solution, a glass connexion, a 3–4 in (7.5–10 cm) rubber tube with a clamp, a rubber stopper with inlet and outlet glass tubes, a 20-ml syringe barrel (filled by releasing the clamp), a long piece of Ryle's tubing, and a metal connexion for the lumbar puncture needle. The connected apparatus was attached to a metal pole clamped to the LP trolley (Fig 1). The Ryle's tubing was clamped with forceps till in use. Irrigations were performed by connecting the apparatus to the LP needle in situ, and repeated in 20 ml till the return fluid became clear. The technique was tried, and improved, on two cases. One was a child of 3 years (organism not isolated), the other a child aged 2 with a relapsed streptococcal meningitis. The method was successful in both.

FIG 1—Method of fitting the lavage apparatus to the LP trolley

Effectiveness of a Wash-out

The effectiveness of each irrigation in reducing the CSF cell count was next studied. The third case was that of a female aged 29 with staphylococcal meningitis and empyema. The cerebrospinal fluid was turbid under a pressure of 300 mm H₂O. Queckenstedt's test was normal. Wash-outs of 40 ml were absorbed easily, and were repeated three times, so that 120 ml was used altogether. A second specimen was taken at the very end, just before the dose of intrathecal penicillin. The count of the pre-lavage specimen was 1,335 cells per cmm while on the post-lavage specimen it was 430.

After 8,000 units of penicillin in 40 ml of distilled water, introduced into the free tube of the rubber stopper, were allowed to seep in through the same apparatus, a steady fall of C.S.F. pressure was noted. The explanation lay evidently in the reduced osmotic pressure consequent on the removal of excess proteins, fibrin, etc., and the dilution of the C.S.F. by the addition of 40 ml of dilute penicillin. In a quarter of an hour the pressure fell from 250 mm to 50 mm H₂O. On the second day the C.S.F. pressure was 100 mm H₂O. 180 ml was used in spinal lavage, and pre- and post-lavage counts were 375 and 50 cells per cmm respectively.

The same phenomenon of rapid absorption of the diluted C.S.F. was noted on this and subsequent occasions. Concurrent with the fall in manometric reading there was increasing concentration in the C.S.F. cell count. Specimens taken 1/4-hourly showed a rising count of 12, 20, 38 cells per cmm. It became a practice to leave the pressure after a wash-out at 300 mm H₂O. This brought the final pressure to 80–120 mm H₂O. Lower pressures were avoided with an inflamed pia-arachnoid as that would approximate the two layers and promote adhesions.

The wash-outs seem to have solved the problem of increased C.S.F. pressure in meningitis, since in a total of 30 of them not once was the pressure markedly high after the first wash out. On the third day it was 130 mm H₂O, and the cellular count 109 per cmm, on the fourth the corresponding figures were 50 and 12. Wash-outs performed on these two occasions showed that they do not provoke pleocytosis when aseptic.

Further Trials

The fourth case was that of a child of 13 months with influenzal meningitis. Lumbar puncture produced only two beads of thick pus. Aspiration was tried without effect. Spinal wash-outs were attempted, but the fluid would not go in freely. Penicillin was given intrathecally, and the following day no more could be done than on the first. The *Haemophilus influenzae* isolated was penicillin-sensitive. The child improved, and was afebrile for a few days. It soon relapsed, and as there was the same difficulty with the lumbar puncture the ventricles were tapped four hours after an intrathecal dose of penicillin. Fluid from the ventricles, however, contained more than 8 units of penicillin per cmm, and the thick perispinal exudate formed no block to the passage of penicillin as was feared, but the *haemophilus* was shown to have acquired much greater resistance to penicillin. The child died next day. Necropsy revealed thick pus below the tentorium and surrounding the spinal cord.

Small concentrations of penicillin were found on the brain surface at necropsy.

In the fifth case of purulent meningitis the organism eluded isolation, but response to treatment and spinal lavage was quick. On one occasion the

FIG. 2—Case 4. CSF cell count after 20 ml wash-out.

FIG. 3—Case 5. CSF cell count after a further wash-out.

FIG. 4—Case 6. Effect of wash-out on the first day of admission.

FIG. 5—Case 6. Effect of wash-out on the second day of admission.

respective cell counts were before irrigation, 580 per cmm after, 70, 210, 525, 650 (Fig. 2). Another irrigation with 40 ml was given and counts on pre-, mid-, and post-lavage specimens were 50, 325, and 375 respectively, showing even better mixing (Fig. 3).

The sixth case was that of a boy of 8 years with pneumococcal meningitis admitted in coma with right-sided hemiplegia. The effect of the wash-outs on the first and second days is shown in Figs. 4 and 5 respectively. On the third day the C.S.F. did not flow freely. Queckenstedt's test became abnormal and lavage impossible. Ventricular puncture gave a freer flow of C.S.F. but no evidence of increased pressure, and no improvement followed. The next day the same difficulty was met with during lumbar puncture, and a large dose of 50% dextrose intravenously to relieve a supposed tonsillar herniation had no effect. The L.P. needle was shifted two spaces higher up and the C.S.F. flow and Queckenstedt's test were here normal. To exclude a delayed effect of the injection another L.P. needle was introduced in the lower spaces, but the same initial state of affairs was still evident and a spinal block was diagnosed. The child died two days later, necropsy revealed no convincing hydrocephalus, no herniation and no organic blocks above the foramen magnum, but there were thick purulent exudates over the convexity of the hemispheres. Unfortunately the spinal cord was not exposed.

Cerebrospinal Fluid Clearance

The seventh patient was a child of 14 months with influenzal meningitis and very turbid C.S.F. (4600 cells per cmm). The organism was only slightly sensitive to penicillin and it was felt that the effect of repeated wash-outs might show to better advantage here. Six daily wash-outs were done and progress was satisfactory. A relapse followed and 7 more daily wash-outs were given. The child recovered fully.

The effect of these wash-outs on pus clearance was studied in this case. All wash-out fluid drained was collected, mixed, and measured. A cell count on a specimen of it gave an idea of the amount of pus removed. Further, the number of millilitres of purulent C.S.F. cleared of pus could be calculated on the same lines as that of urea clearance of the blood. The results of the first six wash-outs are shown in Table II.

Leaking Cerebral Abscess

The eighth patient was a young man of 20 years who had had a cerebral abscess on the right side drained

TABLE II

Wash-out	Pre lavage Count (cells/c mm)	Average Count of Return Fluid (cells/c mm)	Post lavage Count (cells/c mm)	Total Cells Removed	CSF Cleared (ml)
First	4 600	3 125	1 350	246 000 000	53.5
Second	3 020	1 740	1 200	166 000 000	55.2
Third	1 340	450	440	44 000 000	33.5
Fourth	845	275	230	32 000 000	38.6
Fifth	510	127	102	24 000 000	48.5
Sixth	390	130	100	26 000 000	69.0

successfully two years previously. On Jan 12, 1946, he had convulsions culminating in status epilepticus, which later became strictly right-sided. The CSF was acellular and sterile. The next day severe symptoms and signs of meningitis developed and the convulsions ceased. Rupture of a left-sided abscess was suspected, and the CSF was now purulent (8,000 cells/c mm) and under pressure. Table III shows the effect of successive daily wash-outs on this patient. The third wash-out is peculiar in that the average count of the return fluid and the post-lavage count are both higher than the initial count. The abscess must have leaked during the procedure. The patient considerably improved. Six hours after the fourth lumbar puncture (603 cells per c mm) he suddenly developed an acute exacerbation, and the CSF contained 2,700 cells per c mm. Further leakage must have occurred. All specimens of CSF during the illness were sterile. The patient recovered.

TABLE III

Wash-out	Pre lavage Count (cells/c mm)	Average Count of Return Fluid (cells/c mm)	Post lavage Count (cells/c mm)	Total Cells Removed	CSF Cleared (ml)
First	8 000	4 000	3 200	488 000 000	61
Second	6 300	1 330	700	385 000 000	61
Third	1 365	2,180	1 700	215 000 000	157
Fourth	603	246	197	27 000 000	45

Pain in Spinal Wash-outs

The most frequent cause of pain was the low temperature of the solution. Warming the fluid obviated the pain in the majority, but some complained of discomfort or headache when there was much variation in the CSF pressure, and wash-outs then had to be restricted to 20 ml at a time. Another cause of pain may be the position of the needle-point in the spinal theca. On the whole, spinal wash-outs performed by allowing fluid to seep in by gravity are not often painful, and the pain is less than that caused by mixing the CSF with the injected penicillin several times in a 20-ml syringe as recommended by some authorities.

Discussion

Merritt and Fremont-Smith (1937) express themselves as follows: "The conception of acute purulent meningitis as an abscess of the ventriculo-subarachnoid space has previously been presented. It is a well-known principle that the best treatment for an abscess is free drainage. Continuous drainage of the fluid is especially valuable. Irrigation of the subarachnoid space through a needle in the cisterna magna and out through a needle in the lumbar space, or vice versa, will often prevent development of subarachnoid block."

For the reason given earlier, the one-needle method described here was preferred. It is felt that penicillin has not done away with the necessity for preventing deposit formation. Smith, Duthie, and Cairns (1946) state that "the subarachnoid space may become blocked in the early stages of the illness by the rapid deposition of thick fibrinous pus. On the second or third day after the first injection of penicillin most patients show an increase in the

cells in the CSF. It is at this stage that there is most danger of the subarachnoid space becoming blocked." Jepson and Whitty (1946) feel that "the post-mortem appearances tempt one to search for some means of increasing CSF circulation, especially through the basal cisterns."

These views are similar to those that led to the present work on the merits, practicability, and effectiveness of spinal irrigations. Jepson and Whitty also state that "withdrawal of much fluid from lumbar sac or cistern remains of doubtful value in view of the possibility of encouraging herniation through the tentorial hiatus or foramen magnum, especially when cerebral oedema is present, although in our experience withdrawal of 30 to 40 ml by the lumbar route has had no untoward consequences." Withdrawal of similar amounts had no ill effects in the present series of cases. It is felt that the fear of herniation in uncomplicated meningitis has been exaggerated unduly. The frequent use by earlier workers of the double-needle method of spinal irrigation and forced drainage suggests that this is not a serious possibility. Merritt and Fremont-Smith caution people against the removal of large amounts of CSF in cases with increased intracranial tension, except in patients with meningitis, when "as much fluid should be removed as it is possible to obtain." Katzenelbogen (1935) states that "forced drainage was demonstrated by several workers to be innocuous and well tolerated by patients."

If apprehension is felt about the reduction of pressure—for example, in traumatic cases, where cerebral oedema is suspected—a preliminary hypertonic injection may be given. The spinal wash-out should then not be delayed, not only for fear of the pressure rising again but because of the concentrating effect on the CSF and the consequent precipitation of thick exudates. It is felt that this measure will rarely be needed in uncomplicated meningitis.

Of the 30 wash-outs performed none resulted in contamination, as shown by frequent cultures. Apart from clearing pus and organisms, and restoring osmosis to normal, the irrigating fluid may break up commencing adhesions. The CSF pressure is kept down.

Summary

The shortcomings of penicillin in purulent meningitis are discussed.

The seriousness of the formation of deposits of plaques from fibro purulent exudates is emphasized. These result in occluded areas inaccessible to intrathecal penicillin and, because of adjoining thromboses, inaccessible to systemic penicillin.

The possibilities of spinal irrigation by a single needle method, as a preventive measure against these adhesions, are explored.

A safe aseptic technique is described, and its effectiveness is demonstrated. A CSF cellular clearance is calculated.

I should like to express my gratefulness to Drs A. Wilson Gill, B. Maclean, and L. Boyd for their permission to publish the case material, to Dr A. J. McCall for the use of the necropsy reports, to Mr Holdsworth for his help in cell counts, and to the nursing staff for their full co-operation.

PSEUDOMONAS PYOCYANEA MENINGITIS FOLLOWING SPINAL ANAESTHESIA

BY

C. A. VUYLSTEKE, M.D.

(From Medical Clinic B of the University of Louvain)

At Medical Clinic B we had the opportunity of observing four cases of *Pseudomonas* meningitis following spinal anaesthesia, and in the literature we were able to consult* accounts of a certain number of cases. Garrod (1946) asserts that this complication is not as rare as one would think. He rejects the opinion of Livingstone and his collaborators (1943), believing that aseptic meningitis is not due to local irritation but is produced by Gram-negative bacilli not easily detected by ordinary laboratory technique. Evans (1945) deals with the different sources of contamination (the hands of the surgeon, the instruments, the anaesthetic solution, etc.) and describes the method of prevention. Barrie in 1941 had in the course of three months 11 cases of meningitis among 96 patients who underwent hypobaric "percaine" spinal anaesthesia, one of these was fatal. The affection started about the eighth day after the spinal anaesthesia and usually disappeared within eighteen days. The cell count of the cerebrospinal fluid varied from 9 to 11,400 per cmm and the albumin fluctuated in the neighbourhood of 100 mg per 100 ml. Bacteriological analysis showed in one case Gram-negative bacilli, not fermenting common sugars, and producing no indole, but which could not be identified. Smith and Smith (1941) made the bacteriological analysis in Barrie's cases and found the same bacilli in the water, which had passed through a Berkefeld filter and then been used to rinse the syringes. After the filter was discarded no further case was seen. Hewer and Garrod (1942a, 1942b) saw an increasing number of cases of meningitis when the ampoules containing the spinal anaesthetic were sold with gummed labels (formerly the

surgeon. He attributes the infection either to the "novocain" used for local anaesthesia or to the saline employed to rinse the syringe.

In wartime literature (Cairns, 1944) we meet with cases of deep skull wounds communicating with the arachnoidal cavity and producing *pyocyanea* meningitis. Botterell and Magner (1945) describe 9 cases. During the same period they had two cases of *pyocyanea* meningitis in patients whose wounds did not communicate with the arachnoidal cavity but to whom they had applied preventive intrathecal penicillin for slight meningism. They made a bacteriological test of all the phials of penicillin administered during twenty days, before and after use. Only the residue of two of them contained *Ps. pyocyanea*.

Meningitis caused by the *melanogenes* variety of *Ps. pyocyanea* was not reported in the literature consulted. This organism, which is very rare, was identified and described by Radais (1897), and Cassin (1902) found it in a purulent leg-wound. Cultures of the bacillus produce a black pigment which, unlike pyocyanine, is insoluble in chloroform.

Analysis of Personal Cases

We have been able to observe 4 cases of *pyocyanea* meningitis. Infection took place outside our service. Three of these patients were sent to Medical Clinic B for meningitis treatment, in the fourth patient we discovered an ectopic ovary (with perianadixitis) situated under the liver. She had been operated upon elsewhere, and we saw her again, in consultation, subsequent to the outbreak of meningitis, which took place a few days after the operation performed under spinal anaesthesia.

Our cases came from two different surgical centres (A and B). These centres have the peculiarity that the nursing personnel belong to the same staff. Cases 1 and 2 came from Centre A, Cases 3 and 4 from Centre B. The accompanying Table sums up the essential points of the observation.

Table giving Analysis of Cases

Case	Symptoms of Onset	Blood Leucocyte Count	Cerebrospinal Fluid				Course and Treatment	Total Dose of Sulphonamides
			Day	Albumin (mg/100 ml)	Cell Count per cmm	Bacteriological Test		
1	On 8th 15 days after scurocaine spinal anaesthesia. Evident symptoms of meningitis.	12,000	1st 15 d 60 h	180 110 117	1,120 polymorphs 2,230 11,400 "	<i>Ps. melanogenes</i>	Fatal issue in 76 days. Sulphonamide treatment per os (a few intrathecal injections). Nine returns of pyrexia with chills.	419 g. of sulphonamides in 76 days
2	On 8th 4 days after scurocaine spinal anaesthesia.	—	—	—	—	—	From 4th to 9th day penicillin intramuscularly and intrathecally. From 6th to 9th day 6-8 g. sulphonamides daily. Died 9th day.	Slight

4	On 8th 4 days after scurocaine spinal anaesthesia. Another remission 12 h later. No more symptoms. At 10th 6 h chills.	9,500	1st 37 h 77 h 97 h	110 70 50	4,100 700 140 9 "	<i>Ps. pyocyanea</i> " " " "	Two returns of pyrexia. 59th day definitely afebrile. Complete recovery on 92nd day.	740 g. of sulphonamides in 92 days

particulars of the product were etched on the glass itself). The ampoules were immersed in spirit for 60 minutes, but the sterile water in which they were then rinsed gave positive cultures. Worth (1945) mentions the occurrence of staphylococcal meningitis following osteomyelitis of a vertebra after diagnostic lumbar puncture.

Evans (1945) describes two fatal cases of *pyocyanea* meningitis which occurred at three days interval after spinal anaesthesia had been administered by the same

Case Reports

Case 1—A woman 26 years of age was operated on for vesico-vaginal fistula under scurocaine spinal anaesthesia. Symptoms of meningitis occurred suddenly 15 days after the operation. Irregular pyrexia was present, accompanied by chills and she was somnolent, sometimes even semi-comatose. Lumbar puncture revealed *Ps. melanogenes* meningitis. Sulphonamide treatment was prescribed and a total dosage of 419 g. was given over 76 days, the only other treatment was symptomatic. The case presented striking remissions and at times there was promise of complete recovery. The blood serum contained no antipyocyanic agglutinins. The patient

* On one of the days of the lecture at the University of Louvain.

died on the 76th day of her illness after a fresh rise of temperature

Case 2—This patient, a woman aged 24, was operated on for ectopic ovary with perianthecitis, under scurocaine spinal anaesthesia. The fourth day after operation peritonism and meningism were seen. On the sixth day there were evident signs of meningitis, and *Ps melanogenes* was found in the cerebrospinal fluid. Penicillin was given intramuscularly and intraspinally, and medium doses of a sulphonamide were administered from the sixth day. She died on the ninth day.

Case 3—A man aged 41 was operated on for hernia and appendicitis under scurocaine spinal anaesthesia. Symptoms appeared suddenly on the fourth day. The patient complained chiefly of severe headaches. *Ps melanogenes* was found in the CSF. The illness seemed to respond favourably to sulphathiazole treatment, three remissions occurred but the temperature returns were of little importance. On the 100th day of the illness the cell count of the CSF was 83 per cmm (it was 8 000 at the beginning). The patient however, was anything but docile and we were unable to keep him any longer at the clinic. He went home, and very soon had a renewal of pyrexia, with signs of meningitis, urinary retention, and a Cheynes Stokes type of respiration. The patient died 15 days after returning home, having received 1,172 g of sulphathiazole in 114 days.

Case 4—A woman aged 35 was operated on for epigastric hernia under scurocaine spinal anaesthesia. Illness occurred four days after the operation. The patient was treated with sulphathiazole and seemed very soon to improve, but on the 12th day symptoms of meningitis were observed accompanied by general and local epileptiform crises. Lumbar puncture revealed the presence of true *Ps pyocyanea*. The patient was successfully treated with sulphathiazole, the headaches weakened the epileptiform crises diminished and after two minor relapses the temperature was normal from the 59th day, after 436 g of sulphathiazole had been given. Owing to a persistent slightly raised cell count in the CSF we gave her 8 g of sulphathiazole daily for 38 days. She took in all 740 g in 92 days. We kept her under observation for 15 days without treatment, before discharging her. Seven months after her departure she was perfectly well.

Comments

Patients 1 and 2 had been operated on at Surgical Centre A by two different surgeons. The two cases were caused by *Ps pyocyanea* of the *melanogenes* variety. At the same period and at the same clinic two other cases of meningitis occurred 15 days after spinal anaesthesia, these were cured by intensive sulphonamide therapy, but the pathogenic agents were not determined. Patients 3 and 4 were operated on by one and the same surgeon at Surgical Centre B. This surgeon has used the same technique for spinal anaesthesia for the last seven years, and so far no complication has occurred. But all of a sudden 7 cases of meningitis arose. After the appearance of the first case the surgeon intensified the aseptic measures, but, despite this, 6 new cases were seen at the same time. Three of these patients died (one of them is Case 3). Cultures of the CSF of all the cases were made at the surgeon's request.

The pathologist, Prof Bruynoghe (1944), found only two positive cultures (Cases 3 and 4) in one, true *Ps pyocyanea* was developing, in the other, *pyocyanea* of the *melanogenes* variety. The causes of the infection in our four cases are obscure.

The third surgeon (of Centre B), who had 7 cases of meningitis, sent to Prof Bruynoghe a box of scurocaine ampoules five of them were submitted to careful bacteriological examination, but did not reveal the slightest trace of any pathogenic agent. The brushes, however, used by the surgeon to clean his hands were never sterilized. Prof R Bruynoghe is inclined to attribute the cause of the infection to that reason since then the brushes have always

been sterilized, and no further cases of meningitis have been reported from the two clinics. It is interesting to repeat that the nursing personnel of the two surgical clinics belong to the same school.

The three cases treated by us have received very heavy dosages of a sulphonamide—419 g in 76 days, 1,172 g in 114 days, and 740 g in 92 days—without any reaction. The three cases caused by *melanogenes* proved fatal in spite of the fact that two of them (1 and 3) received intensive sulphonamide treatment. Patient No 4, whose meningitis was caused by true *Ps pyocyanea* recovered completely after 92 days sulphathiazole treatment.

Summary and Conclusions

Reports are given of 4 cases of *Ps pyocyanea* meningitis, three of which were of the *melanogenes* variety. Three of them received intensive sulphonamide treatment (by mouth). The fourth had a rapidly fatal issue, and was wrongly given penicillin and only medium doses of a sulphonamide.

One of the cases, caused by true *Ps pyocyanea*, was cured after intensive sulphathiazole treatment (740 g in 92 days).

Pyocyanea meningitis—in particular that due to the *melanogenes* variety—is very rare, and possibly is nearly always of traumatic origin.

The four cases recorded show that spinal anaesthesia may be the cause of the infection. When using that method the aseptic technique therefore can never be too thorough.

These forms of meningitis, in particular those of the *melanogenes* variety, are very resistant to treatment, early and intensive sulphonamide therapy, persevered with because of the frequency of relapses, seems to give the only hope for a real cure.

Thorpe's Dictionary of Applied Chemistry is a work which has gained a well established position in technical literature. Volume VII of the fourth edition is now before us (Longmans, Green and Co price 80s). Its contents run from Iodine to Metallography. The work is primarily intended for consultation by technologists, and the technical aspect of the subject matter is everywhere prominent but the members of the Editorial Board have wisely recognized that pure science is entering the realm of technology in ever increasing measure. They have accordingly made a selection of contributors of special articles from among the most prominent men who are acknowledged specialists in the scientific approach to the respective subjects and these contributors have incorporated the newest information. As examples of the exhaustive treatment it may be mentioned that under Iodine considerable space is given to iodine therapy, and that a full account of Vitamin K is given under its own heading. Other articles worthy of special mention are those concerned with iron and steel, leather magneto-chemistry, mass spectra, and metallography. The references include a most extensive variety of matters extending from such subjects as those named above down to the chemical constituents of the lotus plant and of the homely leek. The eminent position of *Thorpe's Dictionary* in chemical literature is fully maintained in the new edition.

HEPATIC HYDATID CYST CAUSING SUPRARENAL HAEMORRHAGE

BY

L W GODFREY, MB, BS

Senior House-Surgeon Ipswich Borough General Hospital

Hydatid disease in the British Isles is comparatively rare, and almost all the cases that have occurred originated in a small endemic area in South Wales. The following case presented a very unusual clinical picture. I have been unable to trace any similar case in the literature, although Barnett (1941) records haemorrhage as a cause of death in six cases of abdominal hydatid cyst, and Dew (1928) describes a case of haemorrhage due to anaphylaxis.

Case Report

The patient, a fitter and tester aged 29, was born in Abertillery, Monmouthshire. He was described as being delicate from birth, and at the age of 14 was suspected of having tuberculosis and went to live on a farm at Gilwern Monmouthshire, where he stayed for three years. He left South Wales at the age of 21 and had since lived in Ipswich. He had never been abroad.

In July 1944, he had an attack of jaundice, with vomiting and abdominal pain, lasting six weeks. A similar attack occurred in December 1944, and lasted eight weeks. Following these attacks his general health was impaired, he appeared languid, fainted frequently and had considerable flatulence. On May 27, 1946, he developed upper abdominal pain, diarrhoea, and flatulence, followed next day by jaundice and vomiting, with pale yellow stools and dark urine. He was seen by Mr Langley as an out-patient on May 30, when he was noted to be a well built man, with moderate jaundice, clean tongue, and good teeth. The liver was enlarged to 4 in (10 cm) below the costal margin, with slight tenderness in the gall bladder region but the gall bladder was not palpable. Rectal examination revealed no abnormality. At 8 p.m. on June 1 he was admitted to the Ipswich Borough General Hospital, having become dyspnoeic the previous evening and having passed no urine for twelve hours. On examination he was found to be deeply jaundiced and moderately dyspnoeic but not distressed or cyanosed. The temperature was 103° F (39.4° C), pulse 132, respirations 36. His pulse was of poor volume and his blood pressure was 80/50. No abnormality was found in the heart or chest on clinical examination. His liver was enlarged, as above, and very tender, with tenderness spreading down to the umbilicus. The spleen was not palpable.

Investigations—The following results were found on May 30. Urine S.G. 1030, bile + + +. Blood count Hb, 118% R.B.C., 5,240,000 per c.mm. reticulocytes, 0.5%, W.B.C., 10,300 per c.mm. (neutrophil polymorphs 52%, lymphocytes 40%, monocytes 8%). Van den Bergh strongly positive direct reaction. Serum bilirubin, 17.1 mg per 100 ml. Fragility test normal. W.R. negative. Radiographs of the chest on admission showed congestion of both lung bases and raised diaphragm.

A provisional diagnosis of acute hepato renal failure was made, and treatment with intravenous glucose saline, dehydrocholine, and insulin was started. He was also given eucortone in view of the

low blood pressure. Despite all this, however, he died in the early hours of the next morning.

Post-mortem Examination—The cause of the hepatomegaly was found to be a hydatid cyst 5½ in (14 cm) in diameter with multiple daughter cysts (see photograph). All the blood was noted to be fluid, and there were petechial haemorrhages on the visceral pericardium, peritoneum, and pleura. There was also haemorrhage into both suprarenals, more severe on the left. The lungs showed bronchopneumonia. The spleen was slightly enlarged. No abnormality was found in the brain, heart, or kidneys.

Discussion

The probable sequence of events leading to death seems to have been a rupture of the cyst into a large bile duct, causing blockage of the biliary system, jaundice, and lowered prothrombin level. This in turn led to multiple haemorrhages, including destruction of both suprarenals resulting in lowered blood pressure, extrarenal anuria, and death. The high temperature was due to a severe cholangitis in the left lobe of the liver, which can be seen in the photograph. Another possibility is that the whole picture is one of anaphylaxis due to rupture of the cyst into the biliary system, but in view of the absence of urticaria and the lack of eosinophilia this seems unlikely.

The period of infestation is still more debatable. It is tempting to think that the patient became infested while on the farm, where there were many dogs. In this case the cyst would be 12 to 15 years old. In a special investigation into the South Wales cases by the Welsh Board of Health (Howell, 1938), however it was found that the majority of cases occurred in the industrial areas and towns. It is therefore more likely that he was infested at a still earlier age while in Abertillery, and, indeed, this may have accounted for his debility, which led to the suspicion of tuberculosis. His two previous attacks of jaundice were probably also caused by partial rupture of the cyst into a bile-duct. This could account for both the cholangitis and the multiple daughter cysts which Dew believes are always initiated by trauma to the primary cyst, partial rupture into a bile-duct is a common type of trauma.

Summary

An unusual case of hydatid cyst of the liver is described. This caused three attacks of jaundice, in the last of which multiple haemorrhages developed, including haemorrhage into both suprarenals, leading to collapse, anuria, and death.

I wish to express my thanks to Mr G. F. Langley for much advice and assistance in writing this note, to Dr J. Fielding for the post-mortem examination and to Dr J. W. Hunter, medical officer of health, for permission to publish the case.

WILLIAM KLYNE'S *Practical Chemistry for Medical Students* has been prepared with special regard to their requirements. With them the problem is to acquire a complete grasp of the principles and relationships of chemistry in the relatively short time at their disposal. The system by which they are successfully to be taught depends therefore on a judicious choice of subjects for practical experiment and on the presentation of these in a form which is most easily assimilable, free from ambiguity, and which clearly enunciates the principles that are to become the foundation for an understanding of future problems. The success of the author in accomplishing this purpose could only have been achieved by one who had had much experience in teaching the subject to students of that category and who was gifted with discernment to recognize the most effective plan. His experience as a teacher of practical chemistry to medical students has enabled him to develop under a system of continuous re-examination and review an excellent textbook for the purpose required. In its production the author has paid much constructive attention to the clarification of the exercises to be performed and has avoided the common danger of obscuring the theoretical purpose in the instructions for procedure. In this sense the text bears evidence of care to obviate all forms of ambiguity and to make every fact easy of recognition. The opening chapters giving general ideas on qualitative and quantitative work, on manipulation and on appreciation of the findings form an excellent example of how the subject should be introduced. This book, published in Edinburgh by E. and S. Livingstone at 20s. may be commended to all who have to follow the medical student's course of study.

Medical Memoranda

The Filigree Operation for Hernia

For a considerable time the filigree operation for hernia has fallen into disrepute in this country, but during the last two or three years one or two British surgeons have become increasingly interested in this method of treatment and several, though not making use of the actual lattices of silver wire known as filigrees, have nevertheless used sutures of silver or other unabsorbable material in order to repair the damaged inguinal canal.

During the past two years I have had the opportunity of watching the operation performed regularly at the Seamen's Hospital, Greenwich, and have been impressed by the apparent solidity of the repaired canal at the time of operation and also by the first-class results seen in the follow-up clinics there. In spite of this I have been reluctant to adopt the method wholeheartedly because of the great prejudice against it. I decided to discover exactly why the method had been condemned, and, by a combination of both clinical and experimental means, to investigate fully all criticisms directed against it. This would seem to be the only way to determine whether or not such objections really are valid or whether, in point of fact, the dangers and difficulties of this operation have been exaggerated, thus deterring surgeons from making use of what seemed to me to be a method which has a very definite place in the curative treatment of hernia.

After much discussion with my surgical colleagues I have come to the conclusion that the objections to the filigree operation put forward by competent and experienced men may be listed as follows:

- 1 The operation causes marked immediate post-operative pain, and this persists longer than is usual for cases operated on by other methods.
- 2 The filigrees move about in their beds when the patient moves his legs or trunk during convalescence.
- 3 The filigree is capable of movement in the tissues at a later period.
- 4 A rigid structure such as a silver filigree is apt to cause delayed post-operative pain and limitation of movement in the area in which it is implanted.
- 5 Secondary haemorrhage may occur from ulceration of blood vessels in the neighbourhood of the metal.
- 6 Faecal fistulae may be produced owing to the silver coming into contact with the bowel.
- 7 There is a great liability for the wound to become infected.
- 8 If the wound becomes infected the surgeon is faced with an exceptionally difficult problem as the metal cannot come away in small fragments, as can silk but must be removed in toto.
- 9 It is a bad surgical principle to implant foreign bodies in the tissues.
- 10 If there is a recurrence of the hernia following this operation its cure is rendered doubtful and very difficult owing to the presence of the previously inserted filigrees.
- 11 Finally, it has been stated that since hernia is the operation of choice for teaching surgery to beginners a highly skilled technique such as the implantation of filigrees would render the cure of hernia too difficult a procedure to allow surgeons to use it as a teaching ground for their juniors.

This list of objections could easily be divided into two groups—the one capable of solution by careful clinical study of patients before during and after the operation, and the second by animal experimentation in the laboratory.

In the first group may be included the question of post-operative pain, secondary haemorrhage from ulceration of blood vessels in the neighbourhood (in all those cases that I have seen operated on the filigree has been placed in direct contact with the deep epigastric vessels), rigidity of filigrees causing limitation of movement following operation and the special liability to wound infection. Whether or not the filigrees move in the body at later periods can easily be discovered by a

careful study of stereoscopic skiagrams taken shortly after the operation and again at an interval of weeks, months, or years. During the past few months I have collected many skiagrams which should yield useful information on this point.

In the second group experimental methods would seem to be necessary to determine how readily faecal fistulae are produced should the metal come into contact with the bowel and might also be expected to shed light on the question of secondary haemorrhage from vessels in the neighbourhood if such lattices were implanted in direct contact with blood vessels and bowel in the experimental animal. The question of limitation of movement after the use of silver lattices could also be solved in this way.

I hope to be able to investigate the dangers of operating for recurrent herniae in a field already containing filigrees by reproducing a similar set of conditions in some small animal such as a rabbit, and also the difficulties liable to be encountered if removal of filigrees from the tissues should become necessary at a later date.

Though it is true that the use of filigrees can be criticized on the ground that foreign material is being introduced into the tissues, it seems to me strange that this objection carries but little weight when applied to the use of other unabsorbable materials, such as silk, thread, etc. at present employed in so many operative procedures. Therefore it would appear useful to investigate further the relative tissue reactions provoked by introducing such substances as silk, thread, silver, tantalum, etc., into the tissues of the experimental animal. These investigations are at present being undertaken a number of experimental operations having already been performed. I propose, as soon as the investigation is completed to give a full account of this work, together with the conclusions reached.

D M COOPER FRCS

Primary Lymphogranuloma Inguinale in the Female

In countries where lymphogranuloma inguinale is prevalent the primary lesion is rarely seen in females. The following case in which the lesion developed in a contact under surveillance in this country is therefore of interest.

The husband, a Service man, came for examination one month after exposure to infection in Bombay. Three weeks after intercourse he had noticed stiffness in the right groin when walking, and a painful swelling had appeared there. On examination there was a slight mucoid urethral discharge and on the right side of the coronal sulcus was a herpetiform vesicle. The right inguinal glands were enlarged, matted together, and fixed to underlying structures and to skin which was otherwise normal. Clinically the case was typical of lymphogranuloma inguinale. The Frei test was negative at this stage but inclusion bodies were demonstrated in scrapings from the wall of the urethra. Tests for the other venereal diseases were negative.

The wife also was examined on the same day. She had no symptoms and no clinical signs. Five weeks later she returned complaining of swelling in both groins. There were then three small herpetiform vesicles on the lower third of the inner aspect of the right labium minus. A similar lesion was present on the anterior lip of the cervix. Both right and left inguinal glands were enlarged and painful. As in her husband's case, tests for the other venereal diseases were negative, but the Frei test was positive at the end of 72 hours. The genital lesions had also increased in size, though no apparent change in the glands was noted. By the end of ten days the primary lesions had healed spontaneously and the inguinal glands had become smaller. Thereafter she attended for examination every fortnight and nearly four months after the date of the original diagnosis ulceration with oedema and infiltration of the anterior rectal wall had occurred. Inclusion bodies were demonstrated in scrapings from the rectal ulcers.

We wish to thank Dr Robert Lees, Director of the Department for Venereal Diseases, the General Infirmary at Leeds, for permission to publish this case.

Reviews

"CONSTRUCTIVE MEDICINE"

A Future for Preventive Medicine Studies of the New York Academy of Medicine Committee on Medicine and the Changing Order By Edward J. Stieglitz, M.S., M.D., F.A.C.P. (Pp. 77 \$1 00 or 6s) New York The Commonwealth Fund London Oxford University Press 1946

The monographs of this series from the "Committee on Medicine and the Changing Order" of the New York Academy of Medicine are of a very high standard. They are published in co-operation with the Commonwealth Fund, and each writer in turn has been invited to deal with some phase or activity of medicine and relate it to the fast-changing pattern of the life of the American people.

In this book Dr. Stieglitz describes, as he sees them, many of the problems of how medical science can be applied to create a higher level of health as opposed either to curative medicine or to measures designed to avoid a specific infection or group of diseases. In his introduction he is careful to point to the indefinite article at the beginning of the title, and he has succeeded in the book in striking a reasonable compromise between the dogmatic and the mere throwing out of suggestions. Nevertheless such a method has limitations, and in this case, while there are many most thought-provoking definitions and some of the best expositions of the aims of "human eubiotics" or "social medicine" or "constructive medicine"—or by whatever phrase we express ourselves—the author has largely failed to put forward a scheme which is capable of application either by organized social effort or by the individual practitioner. Merely to "snipe" at this monograph in such a way would, however, be quite unfair. The following quotations indicate original thought and a power of simple expression which so many gropers after truth in this subject sadly lack.

"Health has quantitative attributes involving functional reserve capacities. There are various degrees of health. Health is relative. Health can be no more absolute than such states as freedom, slavery, wealth, poverty, beauty, or ugliness. Yet these terms, and many others with abstract connotations, have been used so loosely that the implication of absolute value has crept into our thinking and confused our understanding. Perfect health is an ideal, an abstraction. As such it is essentially unattainable. Nevertheless, like any other abstract ideal, it may be approached."

"For the type of preventive medicine which takes as its objective the improvement of health rather than the lesser goal of avoiding disease, the term 'constructive medicine' has been proposed. The selection of this name was based on the idea that medical science can construct health as well as reconstruct it when destroyed by disease. Basically the treatment of disease is an attempt to reconstruct health."

"It is impossible to prove that disaster is inevitable if preventive care is neglected, for disaster is not inevitable."

"Statistics have little or no emotional appeal, intellectual acceptance of a concept does not activate its application. Thus there has always been a tremendous resistance to any and all preventive effort. The inertia of humanity is immense, mankind learns very slowly indeed."

"In contrast to the negative connotations of prevention in the usual conventional sense, construction of health has positive and aggressive implications."

"There are many disturbances in which infection apparently plays no role whatever. This is particularly true with the so-called degenerative diseases, illustrated by hypertensive disease, arteriosclerosis, hypertrophic arthritis, and the metabolic disorders such as diabetes mellitus, gout, and the thyroid dyscrasias. Prevention of these disorders therefore cannot follow the existing pattern of approach now applied to infective diseases. Yet this pattern has become so fixed in the minds of public health officials that little change can be anticipated unless it is initiated by others."

"Popular support, however, cannot be taken as a guide to intrinsic worth, people rarely become enthusiastic about anything which involves real effort on their part, even though the results more than justify the effort. Tactics will change as our knowledge of etiology expands."

The individuality of the American outlook is well illustrated by the following passages:

"Bitter experience teaches that volunteered advice is almost never followed and gratuitous suggestions usually are ignored. Aid must be sought and paid for to be appreciated."

"Every practising physician old enough to remember the depression has seen repeated evidence of decadence in the sense of individual responsibility, especially among the beneficiaries of free medical service. A social attitude of pampering paternalism exaggerated by governmental policy in the last decade, has encouraged the belief that everyone is intrinsically entitled to health, security, and ease without personal effort. These privileges are supposed to be granted by the ideal state."

While many in this country would agree now that 'the last decade has been marked by an increasing tempo in the appearance of attempts to 'give' health to the people by means of legislation,' the focus of attention has invariably been upon the administrative machinery involved. Bureaucracy flourishes best in the maze of complex administrative organizations. Sometimes the political motives behind such legislation are so obvious that they hardly warrant comment, of course the indolent of the electorate are pleased with the idea of getting something for nothing. Most of these schemes have inappropriately been called, "health programmes," whereas they actually constitute tax-supported subsidies for the treatment of the sick—redistributing the economic burden and adding immense administrative costs.

The arrangement of type in this book illustrates well an unfortunate tendency to neglect chapter subheadings in scientific and serious books. Such books are not intended to be read as novels. The reader wants to refer back, and even the chapter headings give him no guide, while an index is only of value when the book has recently been read. Why have the old-fashioned marginal paragraph summaries disappeared from serious books?

OCULAR PHYSIOLOGY

Physiologie Oculaire Clinique By A. Magitot (Pp. 458 illustrated 750 francs) Paris Masson et Cie 1946

A book published in a foreign language has both advantages and disadvantages. A disadvantage is that one's reading is less rapid than would be the case if it were printed in English. That is where translations of such famous books as Helmholtz's *Physiological Optics* are so valuable. The advantages are that a foreign author has a different literature to survey and to draw information from, because he has access to original articles which are not readily available to English readers. In consequence, his point of view and outlook are different, and his lists of references are also different. The book under review is very useful for this reason. It contains references to many publications with which the reviewer was unfamiliar.

The book deals with the following subjects: The lids, the lacrimal apparatus, the sensory nerves of the conjunctiva, the choroid, the ciliary bodies, the aqueous humour, the vitreous, the intra-ocular pressure, glaucoma, the conjunctival circulation, the cornea, the pupil reflexes, the crystalline lens, the mechanism of accommodation, the innervation of the ciliary muscles, the retina, the retinal vessels and circulation, visual acuity, the perception of colour, the Purkinje phenomenon, the perception of movement, chronaxie, the visual field, the visual centres, the encephalogram, the external eye muscles and eye movements, nystagmus, binocular vision, the importance of proprioceptors. The book as a whole is interestingly written, though it does not seem to contain anything startlingly new. Many of the diagrams are very clearly drawn.

THORACIC DISEASE

Diagnosis and Management of the Thoracic Patient Edited by C. P. Bailey M.D. (Pp. 334, illustrated 24s) London J. B. Lippincott Co 1946

This book from the "American Practitioner Series" is a symposium of articles by various authors, and it suffers from the fault which is so common in works of this type—unevenness. The editorial preface states that the aim of the book is to familiarize "the internist and the general practitioner with modern surgical practice in the management of the more important diseases of the intrathoracic organs." Unfortunately, however, most of the articles are too specialized and too long to be appreciated by anyone who is not himself specializing in chest disease.

The first contribution is an extended account of pulmonary resection for tuberculosis. Although this is well written and documented, pride of place should not have been given to a

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Renal Diseases By E T Bell, MD (Pp 434 35s) London
Henry Kimpton 1946
A monograph co ordinating 25 years study of renal diseases
Includes discussions on toxæmia of pregnancy, renal lesions,
diabetes, and relation of hypertension to the kidneys

DISTURBANCES OF SPEECH AND VOLUNTARY ACTION

Agnosia Apraxia Aphasia Their value in Cerebral Localiza-
tion Second edition By J M Nielsen MD, F.A.C.P.,
Associate Clinical Professor of Medicine (Neurology) University
of Southern California (Pp 292 59 illustrations \$5.00)
New York Paul B Hoeber

This book is much more than a new edition of its predecessor
In it Dr Nielsen has presented the evidence upon which he
has based his published statements on the functions of speech
and voluntary action and the disturbance of these functions
in disease Over half the text is devoted to the evidence—
much of it tedious but most of it necessary The ugly nomen-
clature, abounding with adjectives which has come to surround
this subject makes very difficult reading, although Dr Nielsen
has done his best to achieve uniformity He has presented a
new nomenclature based on the anatomy and physiology of
speech and behaviour, and has found it necessary to devote
over 30 concise pages to the presentation of this new termin-
ology The loss of such terms as 'verbal deafness' for
'auditory agnosia and auditory semantic aphasia,' and the
substitution of 'agnosia subcortical angular, verbal' for
agnosia, subcortical visual verbal leaves us confused, and
when we reach the 87th and last definition which states that
irremembrance visual verbal temporal, is loss of ability to
revisualize words due to a lesion of the temporal lobe, we are
incapable of more The early short chapters give a useful out-
line of the subject, the later ones will only attract the most
senior students of symbolism and speech

The FitzPatrick Lectures before the Royal College of Physicians
of London were to be delivered in 1939 by ARCHIBALD MALLOCH
MD (McGill) and Fellow of the Royal College Owing to the
outbreak of war the actual reading of the lectures never took place,
but Dr Malloch has now placed the lectures under the title of
in his debt by publishing an enlarged version under the title of
*Medical Interchange between the British Isles and America before
1801* In this monograph is included a vast store of information
about the early pioneers of medicine and surgery in the American
and Canadian colonies, and about occasional cases where the com-
pliment was returned The labour involved in this task has obviously
been enormous, but the spirit in which it has been carried out
clearly shows it to have been a labour of love How many people,
one wonders know that the introduction of the monkey puzzle
tree into England (from Chile) was the work of Dr Archibald
Menzies, surgeon to Vancouver's expedition? or that Thomas Dover
of Virginia met Samuel Johnson in London and wrote home a
most exact description of the Great Pyramids? Such and many
more queer and curious items the reader will find in this mine of
recondite information about some hundreds of old time medical
men

TOWARDS DISCUSSION

A Special Representative Meeting was held on Tuesday of this week at B.M.A. House to consider the resolution of Council which was passed at its meeting on Jan 15 in response to the letter of the Minister of Health to the three Presidents of the Royal Colleges. Before this, it may be recalled, the Council, on the basis of the plebiscite returns, had passed a resolution recommending the Representative Body not to enter into negotiations with the Minister on the Regulations of the National Health Service Act. After a long discussion of various amendments the Representative Meeting passed by 252 votes to 17 the Council's resolution, as follows

That the British Medical Association, having considered the final results of the plebiscite and the Minister's letter of Jan 6 to the Presidents of the Royal Colleges and desiring to secure for the people the best possible Health Service, is willing that discussions be entered into with the Minister to that end, provided that such discussions are comprehensive in their scope and that the possibility that they may lead to further legislation is not excluded, and that after the conclusion of these discussions a second plebiscite of the profession be taken on the issue of entering the Service

Mr Bevan's letter was correctly interpreted as a conciliatory gesture. The Council showed its wisdom in responding in the same manner without abandoning the principles for which it and the profession stand. It therefore recommended the Representative Body to enter into discussions with the Minister, "provided that such discussions are comprehensive in their scope and that the possibility that they may lead to further legislation is not excluded." There is no point in reiterating here what the fears and the objections of the profession are. The Minister of Health and the public generally do not seem to us yet fully to have understood the reasons why so many thoughtful members of the medical profession criticize the present Act and are apprehensive because of its implications. What these criticisms and fears are was set forth in the closely reasoned article by Mr Reginald Payne which was published in the *Journal* of Jan 18. That this article has struck a ready response in the minds of many thoughtful doctors is clear from the letters reaching the *Journal*.

The report of the Special Representative Meeting is published in the opening pages of this week's *Supplement*. The report was received shortly before going to press, and comment on it in detail is therefore not possible. It is, however, clear that the representatives, coming from all parts of the country to give voice to the views of the doctors in their divisions and branches, were fully seized of the gravity of the present position, fully deter-

mined not to yield on principle, and quite clear about what is meant by the endorsement of the Council's recommendation to enter into discussions with the Minister. If Mr Bevan rejects the Association's offer then a complete deadlock will be reached. This would be a state of affairs which neither he nor the profession nor the public would welcome. If we are to be just, we must as a profession recognize the fact that Mr Bevan has already made compromises which are not wholly acceptable to his own Party. We must recognize, too, that if the Minister agrees to include clauses of the Act in the scope of further discussions he will probably have to face opposition from his own side of the House of Commons. Nevertheless, this is what the profession is asking him to do and asking the public, through Parliament, to do. This request comes from men who are proud to call themselves workers and who at the moment differ from many other groups of workers in this country in not asking for restricted hours of work at a time when necessity demands the highest output of labour, mental and physical, so that the fruits of victory shall not be bitter. We therefore appeal to the Minister of Health to show high political courage by accepting with all its implications the invitation now extended to him by the Representative Body as the mouthpiece of more than three-quarters of the doctors of this country.

OUR WANING INTELLIGENCE

The distant prospect of a "galloping plunge to intellectual bankruptcy" has prompted the Eugenics Society to publish an "occasional paper" by Sir Cyril Burt on intelligence and fertility.¹ In this admirable booklet are set out the experimental results which strongly suggest the possibility that, if present population trends continue, this country faces a progressive decline in the level of our national intelligence.

The basic facts are clear. The results of intelligence tests which purport to measure the standard of mental ability show a negative correlation ($r = -0.20$) between the intelligence quotient of a child and the size of the family to which he belongs. This means that members of larger families have on the average lower test scores, conversely only children tend on the whole to do better in these tests than those from larger families. The precise nature of the quality of the mind measured by the tests applied by educational psychologists is still not clearly defined, but there seems to be some general factor of cognitive ability which is tapped by all well-constructed tests of intellectual skill. Whatever its precise nature, there is ample evidence that intellectual ability of this type is heritable from parent to child. The correlations between test results in members of the same family are similar to those for height and weight. Between identical twins the correlation coefficient $r = +0.86$, between siblings $r = +0.50$. In fact about 75-80% of the variability in intelligence quotient between individuals can be explained by heritable factors. Further

¹ The Eugenics Society and Hamish Hamilton Medical Books 1947

there is no reason to suppose that high intellectual endowment in this sense and specialized skills or desirable social virtues are mutually exclusive in the same person. Distinguished musicians and artists, talented in the fields of imagination and manipulative technique, are seldom subnormal in general intellectual ability. As might be expected from all this, the children of the professional classes are found to be on the average (but only on the average) more intelligent in this sense than the children of, say, unskilled labourers. In other words, since like breeds its intellectual like, the maintenance of a steady level of the national intelligence depends upon the more intelligent parents contributing enough to the next generation to balance the quota added by parents at the other end of the intellectual scale. This is the crux of the matter, and the serious potentialities of present trends are seen in a comparison of the fertility rates in the different social and intellectual groups in the population. It is evident enough that at the present moment professional families have a net reproduction rate well below that of the working classes. To some extent the negative correlation between intelligence quotient and size of family in a heterogeneous sample from all social classes may be due to the higher average endowment of the small professional families. But there is more to it than that. The same negative association is seen even in a socially homogeneous group like the Yorkshire miners.² This implies that it is the more intelligent parents in every social class who tend to have smaller families. The existence of such a trend in the more numerous working class is the most ominous portent of all.

What then are the social and national implications of these findings? Prognostication in population statistics is notoriously difficult. Much depends on the continued presence of those factors which make for relative infertility—for example, in the professional classes, late marriage, lack of domestic help, anxiety about educational commitments. If, however, the stability of present tendencies be assumed a statistically legitimate forecast of the trend in the average level of intelligence can be made from the results of a sample survey of children in the present generation. There is more than one method of arithmetical approach,² but the results are essentially the same: a maintenance of the present drift will result in a drop of nearly two points on the Binet I.Q. scale between the average of one generation and the next. In a child of 15 a difference of four months in mental age, such as this drop would entail, would hardly be appreciable. But if we consider the extremes and not the average of the frequency distribution along the I.Q. scale a continuation of present trends will result, after a period of fifty years, in a halving of the proportion of scholarship-standard students in our schools and a doubling in the incidence of feeble-mindedness.

These dire prophecies are of course largely based on indirect evidence, of a type which appeals more to the arithmetician than to the administrator. Yet such direct comparisons as have been made between intelligence tests repeated in successive generations have tended to support

the general argument. These surveys may be criticized on social grounds. Burt points out how his own finding among London children of a drop of 0.87 in the measuring scale in twenty years, which is equivalent to 1.3 points in a generation, may be explained in part by the migration of the better stocks and extensive resettlement. Similarly, the rise in the incidence of mental deficiency from 4.6 per thousand to 8 per thousand between 1904-7 and 1925 reported by the Joint Committee on Mental Deficiency³ in 1929 was thought by their medical investigator, E. O. Lewis, to be partly due to better methods of assessment and a reduction in mortality through better care. Burt discounts the possibility that the observed slight diminution of intelligence between earlier and later arrivals in a family explains the association between intelligence and size of family. At the recent meeting of the Eugenics Society (reported elsewhere in this issue) Prof. Penrose made some more soothing comments on the possibility of restitution factors beyond our present ken which tend to maintain the stability of the intellectual mean like other statistical averages such as stature. He pointed out the results of studies among Toronto children, where stature had previously been shown to be negatively correlated with family size—i.e., families large in number tended to be small in average height, yet a survey, made a generation later showed an increase in mean stature. Nutritional improvement in the last few decades has no doubt had its effect. If the analogy be extended to intelligence it seems less safe to assume that improvements in the cultural and educational backgrounds will entirely compensate for the threatened fall in intellectual standards. Indeed, home environment at present accounts for perhaps less than 20% of the variability in test results. It is true that there are still untapped reservoirs of intellectual ability among poorer families, and we must hope that the educational facilities offered by the new Act will ensure opportunities for gifted children irrespective of social class. But as Sir Alexander Carr-Saunders said in this context, it is little consolation for the inhabitants of an island whose shores are being rapidly eroded by the sea to know that they still have some untilled fields.

In Burt's words, "as a nation we should know our resources in mind-power as accurately as we do in man power, iron, and coal," and it is clearly essential to know not only our present assets but also the direction of the trend in our national intelligence. To do that will need large-scale direct comparisons between the results of intelligence tests of children of one generation and the next. Some studies on these lines are already under way, the first very tentative results obtained are certainly not very reassuring. The problem demands for its solution what was pressed for by every speaker at the Eugenics Society meeting—an intensive, large-scale study undertaken by a team drawn from psychologists and psychiatrists, sociologists, and statisticians. The subject is one which engenders considerable emotion, and an accurate and objective assessment of the facts will need the combined endeavour of men trained in all the social sciences.

INFANTILE GASTRO-ENTERITIS A VIRUS INFECTION

The idea that viruses play a part in the aetiology of certain outbreaks of acute gastro-enteritis of infants is by no means new, for it was investigated nearly twenty-five years ago at the Sick Children's Hospital, Great Ormond Street, by a small team of workers under Dr Mervyn Gordon. For lack of clinical material no definite conclusions were then reached. Some evidence has since been brought forward from America that a virus may be responsible for cases of acute gastro-enteritis in infants. More suggestive evidence that infantile gastro-enteritis is merely a symptom of a generalized virus infection has, however, recently been given by Christen and Biering-Sorensen.¹ Since December, 1943, they have been able to investigate some 500 cases of a particularly virulent form of gastro-enteritis which have occurred in paediatric wards and in asylums in Copenhagen. The disease is characterized by its great infectivity for infants under 3 months, premature and debilitated children being especially liable, while no certain case has been observed in children older than 9 months. In several instances the outbreaks have been explosive in character, all the inmates in a children's home having acquired the infection within a week. The incubation period is short, usually from 3 to 5 days. The mortality has been high, and often over 50% of those affected have succumbed. At necropsy the main finding has been fatty degeneration of the liver, associated with a terminal bronchitis or bronchopneumonia. Unfortunately no attempts seem to have been made to transmit the disease to animals, but in 32 fatal cases the central nervous system was carefully examined. In 21 of the fatal cases the cerebrospinal fluid was also investigated. While the protein content was invariably within normal limits in all, in 14 children an excess of round cells was present. Cultures from the cerebrospinal fluid and brain were all bacteriologically sterile.

Histological examination of the brain showed that in 8 cases there was well-marked meningo-encephalitis, in 18 cases there was meningitis without any inflammatory changes in the brain, while in 6 children congestion and oedema of the brain were noted. In those cases which showed meningo-encephalitis, in addition to perivascular infiltration, degenerative changes with neuronophagia were seen in ganglion cells, especially round the floors of the third and fourth ventricles and to a less extent in the cortex. In one case the leucocytic infiltration was so pronounced that in the hypothalamic region it caused large perivascular nodules. Small perivascular haemorrhages were present in all cases examined, whether the associated lesions were those of meningo-encephalitis, meningitis, or merely oedema. No perivascular demyelination was noted. Good photomicrographs illustrate the lesions found. The most extensive meningo-encephalitic changes were present in the youngest age group, whose average age at onset was 14 months, with extremes of from 3 weeks to 2 months. Meningitis or hyperaemia and oedema were found in groups averaging 7 and 5 months.

In searching for previous accounts of brain lesions in association with acute infantile gastro-enteritis it may be noted that a number of observers have recorded changes in the central nervous system. The earliest account of cerebral lesions in association with an epidemic of infantile gastro-enteritis is by Duzar and Balo.² In 7 children they found in the brain oedema, congestion, petechial

haemorrhages, early thromboses, degeneration of ganglion cells, glial proliferation, and in one instance extensive perivascular infiltration extending from the region of the corpora quadrigemina to the medulla oblongata. In 1926 Ribadeau-Dumas and Debray³ described "haemorrhagic meningo-encephalitis" in the brains of infants with severe gastro-enteritis, but as round-celled infiltration was absent it is doubtful whether the lesions can really be termed encephalitic. In sporadic infantile gastro-enteritis Eckstein⁴ described three children with encephalitis, of whom only one was an infant. Goldzieher⁵ reported three cases in infants, Schiff⁶ one case, while Schaferstein and his collaborators⁷ carried out 9 necropsies in one year and found encephalitis in three. More recently Lyon and Folsom,⁸ during an outbreak of epidemic diarrhoea of the newborn recorded oedema, haemorrhages, and perivascular round cell infiltration in the brain substance in two infants.

There is thus considerable evidence that in both sporadic and epidemic cases of infantile gastro-enteritis the changes found in the brain are those characteristic of an infection due to a virus with neurotropic potentialities.

TWO ASPECTS OF MENINGITIS

The prevention and treatment of meningitis are the themes of two papers in this issue of the *Journal*. On page 179 C. A. Vuylsteke, of Louvain, contributes observations on an entirely preventable meningeal infection of which four cases have come under his care. The history of its study may not yet be quite familiar. It goes back to the earliest days of spinal anaesthesia, since when a small proportion of patients given spinal anaesthetics have subsequently developed signs of meningitis, with pleocytosis and increase of albumin in the cerebrospinal fluid, but usually without evidence of bacterial infection as revealed by conventional culture. This was generally regarded as a response to the anaesthetic substance itself, and consequently described as 'aseptic' or 'chemical' meningitis. Whether such a condition really occurs is disputable, but it is now well recognized that a similar spinal meningitis may follow lumbar puncture alone without the injection of any solution, and that both these and at least most if not all of the post-anaesthetic cases are infective. The organism concerned is almost always a Gram-negative bacillus, either *Ps. pyocyanea* or a nondescript *Achromobacterium* of the sort commonly found in unsterile water. Supposedly sterile water obtained from a defective theatre filter was the undoubted source of the organism in the Sheffield series of cases, the reports on which by Barrie⁹ and by Smith and Smith¹⁰ did more perhaps than any other contribution to this subject to clarify it. Subsequent writers whose work is referred to by Vuylsteke, have accepted the view that the rinsing or "dishing-up" of lumbar puncture needles, syringes, or other apparatus used for lumbar puncture or spinal anaesthesia in distilled water is an exceedingly dangerous practice unless the water is autoclaved and from a previously unopened properly sealed bottle. The common assumption that water is necessarily sterile because it is distilled is completely false. It is certainly far better to eliminate the use of such fluids altogether, and it is imperative that all apparatus used should be efficiently heat-sterilized. This includes the manometer if

this should be used in connexion with diagnostic lumbar puncture, it is the passage of cerebrospinal fluid into and back from this tube which probably often accounts for meningitis of this type following lumbar puncture alone. It only remains to add that the failure to demonstrate organisms in cerebrospinal fluid from these cases may often have been due to the inappropriateness of ordinary methods of cultivation. These organisms grow best in very simple media and at a temperature below that of the body. In each of Vuylsteke's patients a *Pseudomonas* was concerned, *pyocyanea* in one, and the rare and unfamiliar *melanogenes* in the remaining three. Intensive sulphonamide treatment produced the only recovery. When available in the future streptomycin will have to be considered as an alternative or in addition. Penicillin is useless for this type of infection.

There is some evidence that *Ps. pyocyanea* meningitis has occasionally been produced by intrathecal instillation of penicillin. The introduction of any fluid into the theca is a proceeding calling for the strictest of all asepsis, and the extensive lavage recommended for the treatment of meningitis by J. A. Nissim in his paper on page 176 is certainly no exception to this. Nissim contends that the two-needle method, whereby fluid is passed from, for example, the cisterna magna to the lumbar region, is less effective for clearing away purulent exudate than repeated flooding and withdrawal through a lumbar needle. By doing cell-counts on the products of these repeated wash-outs he has been able to calculate the equivalent in terms of the original fluid of the pus so removed, and it amounts to a large volume. It is also of much interest that the final instillation after such wash-outs, apparently owing to an osmotic effect, is followed by a fall of pressure. These facts, and the encouraging results in the eight cases treated, should certainly ensure that the method be given a wider trial. Obstruction by the accumulation of thick exudate is the main cause of failure in the treatment of purulent meningitis even when effective chemotherapeutic agents are available, and this appears to be a promising method of obviating it.

FOOD IN GERMANY

All recent reports from the British Zone in Germany emphasize the mounting despair and hostility felt by that underfed, ill-clad, embittered population towards the British. Resentment flourishes and is watered by the tears of self-pity that the Germans so easily shed, criticism of the British has greatly increased recently in cellars, on public platforms, and even in the German Press. One might say that the breaking-point is being approached were it not that there is nothing left unbroken. A recent nutrition survey carried out by a combined British, United States, and French committee reports that "while part of the population of the cities of the three Zones of Western Germany is in a fairly good nutritional state, a significantly large proportion is in an unsatisfactory condition, and of those an increasing number show signs of severe under-nutrition." The purpose of the survey was to compare the nutritional state with that existing in August, 1946, to estimate the effect of the authorized ration allowances on the state of nutrition, to assess the quantity and effect of available unrationed food consumed in the three Zones, and to determine the extent to which available food is allotted in accordance with nutritional requirements. We append a table of the calorie value of the official daily ration scales current in November, 1946.

In August, 1945, this committee expressed their opinion that the minimum food allowance which could safely be

issued if malnutrition was to be avoided was the equivalent of 2,000 calories daily. This has often not been obtainable, and the weights of German adults are now significantly lower than they were a year ago. Hunger oedema, though mild, has increased, and cases are occurring in younger age-groups than formerly. The only group relatively unaffected by the food shortage is that of children under 7, partly because their ration approximates more closely to their requirements than does that of other groups, partly

Calorie Value of the Official Ration Scales Current in November 1946

because their mothers share their own rations with them. The committee recognized that the 2,000 calories recommended would not immediately be available, and they set the figure of 1,550 calories as the lowest at which life could be maintained. Experience during the last year has proved that this recommendation was fairly correct, nevertheless, the provision of 1,550 calories is not in itself sufficient, and severe malnutrition has been avoided only by recourse to unrationed foods and the black market. It was found that this basic ration, when supplied to prisoners, whose physiological needs are probably less than those of men leading a free life, was insufficient to prevent the effects of starvation, and it is necessary to allow men in gaol to receive food parcels from outside. The seriousness of the present position is in part due to the depletion of goods suitable for bartering on the black market.

The ration of underground coal miners provides approximately 4,000 calories, but, though this is theoretically sufficient and though they have opportunities for bartering coal, malnutrition has not been prevented. The miner is part of a family group, and much of his ration goes into the family pool—a fact borne out by experience in the French Zone, where the provision of additional food for miners' families has resulted in improved nutrition in the miners and an increased output of coal. The population as a whole is remarkably free from the observable effects of vitamin deficiency diseases, and the unsatisfactory state of nutrition is due almost entirely to lack of calories and associated protein, with consequent loss of body weight, weakness, and ready fatigue as the commonest manifestations. The committee recommends that, in addition to increasing the ration scales, school-feeding programmes should be extended to include all children, that the British authorities consider giving more food to the families of coal miners, that calcium carbonate be added to flour in the proportion of 1 part in 280, and that, in view of confusion over the computation of calories, a uniform scale be implemented as soon as possible.

Sir James Walton will deliver the Hunterian Oration on "Hunterian Ideals To-day" before the Royal College of Surgeons of England (Lincoln's Inn Fields, WC) on Friday, Feb 14, at 5 p.m. Fellows and Members of the College are invited to attend.

Nova et Vetera

SIR THOMAS MORE AS HEALTH REFORMER

SIR ARTHUR MACNALT, in a Chadwick Lecture given on Oct 8 at the Royal Society of Tropical Medicine and Hygiene, said that Sir Thomas More was a great forerunner of Edwin Chadwick in public health reform. Renowned as saint and martyr, he was an eloquent orator, an eminent statesman and legislator, Speaker of the House of Commons, royal ambassador and Lord Chancellor, a master of English prose, and a classical scholar. These great gifts united in one man had obscured his teaching and work in public health and social medicine.

Thomas More (1478-1535), son of Sir John More and Agnes Grainger, was educated at a City school, and brought up in the household of Thomas Morton, Archbishop of Canterbury and Lord Chancellor. He was an undergraduate at Canterbury Hall, Oxford, where he came under the influence of the humanists Linacre and Grocyn. In 1496 he became a member of Lincoln's Inn and was called to the Outer Bar in 1501. He met Erasmus in 1499, the beginning of a lifelong friendship. Thomas More learned much from Linacre and his teaching led him to become a pioneer in public health administration. Reference was made by the lecturer to More's interest in medicine, as exemplified in his writings and to his friendship with physicians, notably John Clement. In 1510 More was appointed one of the Under-Sheriffs of the City of London, which gave him opportunity to advise the Corporation on sanitary reform. This interest in public health was further shown by his appointment in 1514 as one of the Commissioners of Sewers along Thames Bank between East Greenwich and Lambeth. He worked for the improvement of England's water supplies and refers to London's water supply in *Utopia*.

Utopia was partly written at Antwerp when More was ambassador to the Archduke Charles, afterwards Charles V, in 1515 and was completed in England. *Utopia* is the imaginary Commonwealth of the Renaissance idealists. It advocates many social reforms, in addition it devises a most complete system of health reform which was greatly in advance of his time, and in some respects in advance of our own time. Illustrations were given by Sir Arthur MacNalty of More's interest in the sick, infirm, aged, and destitute. He hired a house in Chelsea for infirm, poor and old people, and maintained them at his own expense. In 1518 both plague and sweating sickness were rife in Oxford. King Henry VIII appointed More to supervise the health measures to be taken. He controlled the outbreak by notification and segregation, and the first plague order issued in 1545, codified his previous regulations and instructions. It contains the germs of all subsequent preventive practice.

More was an advocate of hospital reform which he outlines in *Utopia*. In his *Supplication of Souls in Purgatory* (1529) he opposed the folly of abolishing the English hospitals. Henry VIII ignored More's advice and the 'Five Royal Hospitals' of London were only preserved by the action of the City Corporation. More succeeded Wolsey as Lord Chancellor, but resigned in 1532, as he disagreed with the King's ecclesiastical policy. In 1534 he was imprisoned in the Tower, indicted for high treason in 1535, found guilty on perjured evidence and executed on Tower Hill—the blackest crime ever perpetrated in England under the form of law.

BERNARD (1813-78) PASTEUR (1822-95)

Claude Bernard ou l'Aventure scientifique By Raymond Millet
Illustrations by G. Bourdier (Pp 312, illustrated) Paris
Les Editions de la Nouvelle France

Pasteur By Henri Mondor (Pp 189 illustrated) Paris
Editions Correa et Cie

During the nineteenth century France was fortunate in having such outstanding, able scientists as these men, whose brains were pregnant with original speculations and who were making discoveries on correlated lines of thought. They encouraged each other. Thus in 1867, Louis Pasteur wrote to Claude Bernard: "I have felt such a lively and true satisfaction about your work that my admiration is confirmed and increases to such an extent that I cannot resist the desire to write my impressions. In seeing so much enduring progress unrolled before my eyes, with such certainty of method, I feel the sacred fire of science burning within my heart." To this Bernard replied that such praise from Pasteur, a savant who was such a leading experimentalist in science, made him proud and happy. What physiology owes to Bernard, pathology and bacteriology owe to Pasteur.

The life of Claude Bernard was written in 1899 and there have been several biographies of Pasteur. A lively interest in them is maintained in France, as shown by these two books, both of which have a popular aspect while paying much attention to the physiological and biological epochs through which Bernard and Pasteur led their country in each instance in spite of much opposition.

Claude Bernard made valuable researches on secretions of the alimentary canal, the pancreatic juice, and kindred subjects. His *Lessons in Experimental Physiology Applied to Medicine* (1855-66) is still a standard work. In the early stages of Bernard's career, while still working as a writer of dramatic plays, he was fortunate to come under the influence of Prof. François Magendie, a leading French physiologist and member of the Academy of Sciences. Magendie told his young student to found all his knowledge on experiments and not to believe in theories but only in facts. M. Millet's memoir of Bernard is a study of an acute mind and how it evolved many valuable deductions from practical observations. The author traces the steps of Bernard's laboratory experiments, showing how he did not cease to develop his hypotheses till they had become certitudes. Bernard and Pasteur followed the same rules of work—keen observations, closely reasoned experiments and clear conclusions from brilliantly conceived premises.

Dr. Henri Mondor's *Pasteur* is a review of the savant's life. He describes the various steps in research made by Pasteur, beginning with isomerism and the discovery of the left-hand tartrates, which made him the leading chemist of his time. Soon afterwards he was made professor of physiology at Dijon and published his famous *Traité on Lactic Fermentation*. Using Lister's aseptic and antiseptic methods, he turned his attention to the study of infectious diseases, isolating and cultivating bacilli by immunization. In 1882 he first cured hydrophobia by inoculation with an attenuated virus; he could not isolate the organism, though he was successful in locating its position in the nerve centres. In the latter pages of his book Dr. Mondor tells of the quarrel Pasteur had with Liebig over the role of yeast in alcoholic fermentation. Throughout his life Pasteur had to combat a crowd of sceptics and adversaries, but his end was crowned with universal acclamation in the opening of the Pasteur Institute in 1888 as a world centre for the cure and prevention of disease.

The importance of these two men of science, and the clarity of expression used in depicting their work and lives, make these books on Bernard and Pasteur more than ordinarily instructive and pleasant to read.

Garrison characterized PIERRE FAUCHARD'S *Le Chirurgien Dentiste* (1728) as one of the three most important books in the history of dentistry, and Mrs. LILIAN LINDSAY has now put all English-speaking members of her profession under a debt by translating the second edition (1746) with the title *The Surgeon Dentist or Treatise on the Teeth*. That edition gave the first account of pyorrhoea alveolaris, and Fauchard was also the first to employ orthodontic procedure in the treatment of malocclusion. Mrs. Lindsay's version, published by Butterworth and Co., Ltd., at £2 2s., appears as a sumptuous volume. It is printed in this form as a tribute to her from the British Dental Association in commemoration of fifty years' membership of that body and of her devoted work as honorary librarian (1920 to 1946). It is adorned with reproductions of a portrait of Fauchard and of the original plates which accompanied the two volumes of the second edition. Recalling that this book has held the first position among dental literature for over two centuries and that its author has been acclaimed as "the father of dentistry" for almost as long a period, she comes to the conclusion that Fauchard either came or was the first to use the term "chirurgien dentiste." At the date of the second edition he had become the leading dentist in Paris. The manuscript of his book was discovered by Dr. George Vau in 1892 in the library of the Faculty of Medicine in Paris. One of the most valuable parts of this work, the case records with Fauchard's reflections upon them, give the reader an insight into his movements and his method of practice as well as the standard of the practice of dentistry accepted at the time. This is the first time the entire text has been translated into our language and Mrs. Lindsay's endeavour throughout her pious task has been to preserve as much as possible the style of the original. Fauchard emerges to the reader of these pages as a man of the highest character, inventive, disinterested, and resourceful, dedicating himself to the advancement of dental knowledge and craftsmanship.

Reports of Societies

INTELLIGENCE AND FERTILITY EUGENICS SOCIETY SYMPOSIUM

A meeting of the Eugenics Society was held in the Royal Society's rooms on Jan 21, with Lord HORDER in the chair, to discuss the relation of intelligence to fertility.

SIR ALEXANDER CARR-SAUNDERS, who opened, said that at the time the Eugenics Society was founded by Galton nothing was understood about the mechanism of intelligence. It was suspected that there was differential fertility and that social groups with varying reproduction rates were differently endowed, but it was largely guesswork. That phase of guesswork had now passed. The evidence which pointed to a decline in national intelligence rested on two series of observations. The first was that all social groups did not make equal contributions to future generations and that differential fertility rates existed within and between social groups. The second was that different social groups were differently endowed. It was sometimes suggested that the intelligence which was taken into account in tests was only one of several valuable mental qualities and that these others might be unaffected by differential fertility. This assumed that valuable mental qualities were not correlated, but if he was correctly informed the evidence was the other way about, persons who were knowledgeable in musical, artistic, or literary directions, for example, usually had also a degree of general intelligence above the average.

Some people declared that there was no need to be alarmed about the downward trend disclosed by some investigations, seeing that there was a large amount of unused or inadequately used intelligence in the population. It was true that there was a reservoir of insufficiently trained or utilized intelligence, but he doubted whether islanders who saw the constant erosion of their coast would be comforted by the reminder that they had some undeveloped hinterland. A decline in national intelligence was an actual loss, irrespective of whether full use was being made of the intelligence available. There were many aspects of this matter which needed most careful scrutiny. A difficult inquiry was only at its beginning, but it was a happy circumstance that universities were now equipping themselves with psychologists, geneticists, statisticians, and sociologists, for in the investigation of such a problem, which was liable to arouse emotion and therefore prejudice, it would be valuable to have contributions from as many independent centres of research as possible.

Declining National Intelligence

SIR CYRIL BURT said that forty years ago this subject would have aroused deep controversy, to day there was a converging agreement, chiefly for the reason that psychologists were no longer content to offer mere opinions but based their conclusions on objective methods. Nevertheless, the conclusions still rested largely on deductions which there had been very little direct evidence to confirm. The deductions were founded on two premises: (1) that tested intelligence might be assumed to be more or less innate and inherited, and (2) that tested intelligence was negatively correlated with fertility. Most psychologists would agree that for practical purposes there was a common factor of intelligence. The second step was to prove that this common factor was inherited. A good deal of evidence for this was available along different lines of approach. All practical psychologists checked their methods of test by other study, and it was a very reliable estimate that at least 50% of the variants found in the tests were due to inheritance. If some parents were more intelligent than others, and these parents were, on the average, producing smaller families, it followed that the intelligence in each successive generation must be slowly declining. The important thing was the rate of decline, and here was another difficulty: that the tests for the most part had been done on children—not on their parents.

Sir Cyril Burt mentioned some investigations of his own which seemed to indicate a loss of about two points I.Q. on

the Binet scale in a generation, and very much the same figure had been reached by Prof. Godfrey Thomson and other investigators. A loss of two I.Q. points might not seem very much. It meant that the children at a given age would be about four months retarded as compared with their parents at the same age—a difference which might be elicited in tests but hardly observable in practice. The important thing, however, was the tail ends of the distribution—the numbers of very defective and dull children on the one hand and those with high intelligence on the other. If this rate of decline continued for fifty years the number of feeble minded would be doubled and the number of scholarship winners halved. But this prediction rested on an inference from certain premises, and so far there had been no direct verification of the result. In some London areas tests of intelligence had been carried out at intervals, and a slight decline had been found, but the size of the decline was nothing like that he had just mentioned, and London with its migrant population was a bewildering area in which to carry out such researches. He could not help thinking that if there had been this alteration in the number of defectives on the one hand and the number of scholars on the other it would not have escaped the notice of education officials, school medical officers, and teachers, many of whom had had in their schools in years gone by the parents of the children they were now teaching.

But these criticisms, while they bore on the calculated size of the decline, did not prove that no decline had taken place. He thought there was a high probability that an important and serious decline of some sort had occurred, and, if so, no time should be lost before investigating it. What was needed was further research by a co-operative team of psychologists to advise and apply the tests, statisticians to decide the best methods of statistical analysis, geneticists to correct any crude notions of heredity, and experts trained in social field work to save psychologists from the pitfalls to which they were liable when interpreting social data.

Restitution Factors

Prof. L. S. PENROSE said that differential fertility was probably not a recent phenomenon, and if it had gone on unmodified for a great length of time it would mean that the race was becoming progressively less intelligent. But it seemed reasonable to suppose that there were restitution factors which tended to keep intelligence more or less at the same level. Some investigators had suggested that the firstborn in the family was likely to be the most intelligent; the level of intelligence decreasing as the family grew in number. If that was so it would mean that in an era of large families the general intelligence would fall, but when, as now, families tended to be smaller very often restricted to one child, the result would be to raise the level of intelligence. It was quite possible, again, that there were a number of recessives responsible for high intelligence as well as for low. After all, the high intelligence was equally a deviation from the mean. In showing how confusing these estimations were he mentioned that in Toronto a number of biometricians had measured the stature of 10,000 children (the hereditary factor was supposed to determine stature up to 90%), and it was found that the average stature diminished with family size. It was inferred from this investigation that in consequence of differential fertility in one generation in Toronto the children on the average would be 1.9 cm. shorter than their parents. On the other hand, also in Toronto, though on smaller samples, children had been measured over a period of 15 years, and it had been found that during that time there had been a gain of 3.8 cm. in stature.

Lord HORDER found the data on the objective side very meagre and mentioned various pitfalls and fallacies surrounding the whole subject. He hoped that a proper distinction was being made between fertility and fecundity.

The discussion was wound up by Prof. GODFREY THOMSON who delivered the Galton lecture on the subject a year ago. He pointed to the necessity of bearing in mind that any decline in intelligence in the members of larger families might be due not to inherited characters but to relative lack of cultural opportunity. Another reassuring point was that, although at least 50% of the variants might be due to inheritance (indeed, the figure was generally acknowledged to be higher, even 60 or 70%), it was still possible that the remaining 30 or 40%

due to educational, environmental, or nutritional factors might have a decisive influence

Families of the Famous

One speaker in the discussion, Mr BRAMWELL said that he once took the trouble to study the family history of the small group of distinguished individuals who had at various times received the Order of Merit (Civil). They came from Victorian families having an average of 5.5 children, but the average size of their own families was only 1.5, and among these persons, of course economic causes could not be invoked as an explanation of family restriction. An investigation had also been made into the families from which bishops came. About eighty years ago these families also consisted of an average of 5.5 children, but the later years of the nineteenth century saw a decline and at one time the figure fell to 1.7, though it had since risen.

CORD ROUND THE FOETAL NECK

Mr JOHN HAMILTON read a short paper on this topical subject at a meeting of the North of England Obstetrical and Gynaecological Society held in Manchester on Dec 6, 1946. This condition could be diagnosed before and during labour by the marked slowing of the foetal heart rate when the foetal head was pushed down into the brim of the pelvis. With the presence of this sign, the life of the child would be seriously jeopardized if delivery were allowed through the natural passage and it was suggested that this should be an indication for Caesarean section. In three cases delivered abdominally and where this sign was present he had confirmed the shortening effect of the cord, which was wound many times round the infant's body at the time of the operation.

Mr A GEMMELL described an unusual case of adherent placenta which he was unable to separate at an operation performed six weeks beyond term for the removal of a dead full term foetus from a uterus which could not be made to evacuate itself. The placenta was left *in situ* and gradually became absorbed enabling the patient to become pregnant again two years later. This second pregnancy was concluded with success at the thirty-fifth week by Caesarean section, performed because the baby was presenting as a breech and because of the strange conditions found at the previous operation.

Dr R M CORBET described two cases of melanoma of the vulva and Dr S B HERD the case of a woman who died of fits of uncertain causation in early pregnancy.

CARDIAC PROBLEMS IN RECRUITS

At a meeting of the Manchester Medical Society on Dec 4, 1946 Prof CRIGHTON BRAMWELL referred to the importance of murmurs in the diagnosis of heart disease in recruits. There was still a difference of opinion on the significance of apical systolic murmurs, but all cardiologists were agreed that a patient's activities should not be limited merely on account of such a murmur unless there was other evidence of heart disease. He outlined a working hypothesis for classifying by auscultation cases of mitral stenosis in three groups—severe, moderate, and slight. There was a difficulty in differentiating between the murmur of slight mitral stenosis and the roughened and accentuated first heart sound heard in conditions such as thyrotoxicosis, in which that organ was overactive. When the diagnosis by auscultation was in doubt x-ray examination of the heart was very helpful.

Members of medical boards often had difficulty in differentiating between a systolic and presystolic murmur. In this matter the character of the murmur was helpful, as was the fact that the presystolic murmur was always associated with an accentuated first heart sound. Duplication of the second heart sound at the apex used to be regarded as evidence of mitral stenosis, but out of 835 consecutive cases examined during the war this sign was present in 19% most of these men appeared to be perfectly healthy. In a consecutive series of 39 cases referred by medical boards on account of cardiac enlargement for which

there was no obvious cause, x-ray examination failed to confirm the presence of enlargement in 26. In seven of the remainder cardiac enlargement was trivial. Of the other six, in whom enlargement was more pronounced, two were youths of 19 and 20 who enjoyed perfect health and whose heart rate at rest was 50. Evidence from comparative physiology suggested that in these two cases the bradycardia and cardiac enlargement were related and that the latter was not pathological.

Prof H S RAPER referred to the striking finding of very high pulse rates in small compared with large animals, and suggested that the conclusion might be drawn that small animals were more dependent on a rapid action of the heart to maintain their blood pressure than larger animals, which obtained the desired result by the stabilizing effect of their comparatively larger arterial tree. Dr M C G ISRAELS suggested that the recruits sent from the medical boards were not really representative of all the problems with which medical officers in the Services had been faced after the increased popularity of mass radiography. He exemplified the radiological finding of a prominent pulmonary conus or enlarged heart in recruits with no other evidence of past or present heart disease, and in others the finding of definite diastolic murmurs of aortic incompetence with no signs of heart failure.

Symptomless Cardiac Murmurs

Dr W A RAMSEY described cases of student nurses with systolic murmurs over the cardiac apex who completed the whole of their strenuous training without showing any signs of cardiac decompensation. Dr S ALMOND referred to young recruits who presented loud systolic murmurs at the apex and other areas. Haemoglobin estimations on these cases often showed values below 60%, the heart murmurs disappearing after the anaemia had been corrected. This should not be ignored by those examining otherwise healthy recruits.

TRICHOMONAS VAGINAL INFECTIONS

On Dec 19 1946, Mr PATRICK RUSSELL discussed trichomonas infections before the Devon and Exeter Medico-Chirurgical Society. The disease was primarily one of the vaginal walls—a granular vaginitis—and a watery, offensive, bubbling vaginal discharge was often accompanied by oedema and congestion of the vulva. It should be borne in mind that the infection often coexisted with a chronic cervicitis or gonorrhoea. Diagnosis depended on identification of the parasite. Smears should be taken by inserting a glass pipette or bakelite spoon into the vagina, and be examined directly in a wet film. Neither a speculum nor a finger should be passed into the vagina beforehand. The parasite had been found in the prostate, the bladder, and (doubtfully) in the Fallopian tubes. It was possible that the trichomonas harboured in the intestine was identical with that found in the vagina, and might account for recurrences. Although the infection occurred in virgins, he thought it should be regarded as a venereal disease. The parasite might be found in the male, when it occurred in bulls it was apparently incurable, and the bulls had to be slaughtered.

Local treatment with such preparations as "devegan" or "SVC" in tablet form was fairly satisfactory, but it was better to swab the vagina dry and insufflate it, under direct vision, with the chosen medicament used in powder form. Two treatments a week without intervening douching should be carried out. Oestrogens might have an adjuvant action in these cases. Virgins were best treated by irrigation with weak acriflavine solution. Great care must be taken not to insufflate under pressure because of the very real risk of fatal air embolism. Three negative wet films taken in the post-menstrual phase might be regarded as proof of cure, but recurrences are frequent.

The *British Dental Journal* is now issued in a new and enlarged format. Future numbers will include articles not only of scientific interest but also on topics arising from dental practice, as well as general dental news. In the issue of Jan 3 an interesting summary of the journal's history is followed by articles on 'Dental Disease in Animals,' by Sir Frank Colver, and on 'Penicillin in Maxillo-facial Injuries' by Mr N Holland.

Preparations and Appliances

THE TRAP-JAW PRINCIPLE IN SURGICAL FORCEPS

SIR HENEAGE OGILVIE, K B E, M Ch, F R C S, writes

Forceps intended to take a firm hold of tissue, whether dissecting forceps, haemostats, holding forceps of the Ochsner type or gall-bladder forceps, depend for their security on the forcible apposition of two parallel surfaces. Since the blades are hinged, the surfaces of the jaws are parallel in one position only, usually the completely shut one when they are not in use, when they are applied, the blades are forced apart to the extent of the tissue compressed between them in a gap which is wedge-shaped, holding the gripped tissue firmly at the hinge

FIG 1—Lane half toothed dissecting forceps

end, less firmly towards the points. Many mechanical devices have been introduced to prevent slipping: the surface of the jaws are roughened, usually by a transverse ridge and furrow pattern, the blades are arched to provide a spring pressure throughout their length or in-toed to make a contact at their points first, or they occlude at the tip only as in the Joll haemostat. All these devices fail to hold a tube such as a large vessel, the duodenum, the appendix, the ureter, the cystic duct or the colon if it is cut across flush with the blades

FIG 2—Lane non-toothed dissecting forceps

only when a flange of uncrushed tissue is left protruding beyond them is the hold a safe one.

The instruments I am describing have hollow blades with a narrow, rounded rim. The rim holds a strip of tissue in compression, while the hollow accommodates an uncompressed part that prevents slipping in the same way as does a projecting flange of tissue in the usual design. The pattern has four advantages over the usual compression type. The blades can be made narrower while giving equal security: the tissues

FIG 3—Modified Moynihan cholecystectomy forceps

held can safely be cut flush with the blade (an advantage in the case of infected portions of the alimentary canal), the hold of tissue, even when cut flush, is more secure, and less devitalized tissue is included in a ligature.

Of the instruments illustrated, the dissecting forceps and the Mayo Ochsner forceps differ from their normal prototypes in the design of the jaws only.

The gall bladder forceps have been modified in three particulars, they are half an inch longer, they are lighter, and they are narrower in the blade than the standard Moynihan pattern. I use these forceps in operations of every type when working in the depths of a wound, both for blunt dissection round a

corner, as when clearing the ureter, the lateral attachments of the rectum, the biliary ducts, the left gastric artery, the oesophagus, and for catching any deeply placed vessel previous to ligation. The added length gives better access, the narrow blades improve them as dissectors, and the hollow jaws give that security so essential in situations where a second grab at a cut vessel or duct is an experience to be avoided.

FIG 4—Curved on flat haemostat

The haemostats have hollow blades, and the narrow bite and added security this allows. They have two further advantages over any other pattern I know.

First, they have a 30° curve on the blade to fit them for the two uses of a haemostat, a picker up of small bleeding points or a compressor of wide oozing surfaces. The first task requires the application of the points only at right angles to a surface, the second uses the blade applied parallel to a surface. Straight haemostats are wrong for both purposes, as

FIG 5—Straight Ochsner forceps

illogical as any straight tool. Man naturally uses precision tools in front of his body and below his eyes, that is at a point about 30° in front of and below his elbow. Tools meant to work in the horizontal plane, such as golf clubs, hockey sticks and spoons, are therefore curved to allow their working surfaces to lie horizontally, those used either horizontally or vertically, such as forks or ink erasers, are similarly sloped and used either way. The only straight tools are those driven by

FIG 6

a hammer or by the weight of the foot, the sternum, or the shoulder. These haemostats, like forks, are right in either plane.

Secondly, their whole construction is flat and light, to allow up to two dozen to be stacked on one peg of any instrument rack.

These instruments are made by Down Brothers.

Correspondence

The Plebiscite

SIR—We personally do not approve of the Health Service proposed by the recent Act of Parliament and accordingly voted against negotiating with the Government.

We have now seen the result of the plebiscite, which shows that the younger members of the profession wish for negotiations. We are young doctors ourselves and feel strongly that it is the opinion of the younger members which will eventually determine if the Health Service is going to function. We do not consider the majority against negotiation sufficient to warrant refusal to negotiate.

We have our livelihood as well as our principles to consider, and shall have to join the Service if other young doctors are going to do so. We now feel negotiations should be made to obtain the best conditions for the Service.

A further plebiscite can be made when details of service are available. Only the refusal of an overwhelming majority can render the Health Service unworkable—We are, etc.,

JOAN WAGSTAFF
HELEN WAGSTAFF

Chingford Essex

National Health Service Act

SIR—The *Journal* of Jan 18 contains three notable contributions on this vexed and much argued subject. I feel that pride of place must be accorded to Mr R T Payne's article (p 102) which is a very masterly account of the position at the present time, not only in regard to the Act but also to legislation in general. This article deserves the closest attention of all affected by the Act—both practitioners and students—for it places the onus where it ought to be namely, on the shoulders of the Minister, and not where he is apparently trying to place it by offering to negotiate now within the principles of the Act—namely on ours. Mr Payne has established the fact that bureaucracy is here and therefore that our liberty as citizens is in danger. I would add that, if a halt is not called now then the Gestapo is not far off. It is happening here.

The letters of Dr Doris M Odum (p 109) and Dr A E Moore (p 110) point the way to calling a halt, at any rate in so far as this piece of legislation is concerned. I should go further however, and after adding one point to theirs—that representatives on central and other councils must be elected, and not appointed by the Minister under any circumstances—would suggest that we stand firm against any coercion or other onslaught and give an uncompromising and unyielding No until these objections are met in full. I believe that the Minister must heed us but only if we are resolute, for I cannot see that he can do otherwise. Without us his Act must fail, and if we really do disagree with it let us say so clearly. This opportunity of rendering public service is a great one, and we ought to grasp it—I am, etc.,

Bakewell Derbyshire

HUGH G WATSON

SIR—There seems to be much muddled thinking and shilly-shallying about this Health Act and what we are to do about it. Therefore I believe it is worth while to clarify the issues (in spite of the intervention of the three Presidents, who are not leaders of the profession and have no mandate from their own colleagues). First the majority of those voting No is a greater majority of the profession than the Government enjoys of the electorate. Secondly there is about the same percentage of non voters in the profession as in the electorate. Thirdly, the majority of the No voters believe for various reasons that the Act is a bad one (though parts are good) and the bad is so bad that it nullifies the good and will inevitably lead to evil. Fourthly this is certainly a political issue though not a party political issue, as far as the doctors are concerned, as the No voters would resist such evils imposed by any Government of Right Left or Centre. Fifthly, if, as I believe, we desire a good and worthy comprehensive service, we must

fight for our beliefs and principles and not negotiate on details and mere regulations and so cast our principles away. Only by so doing will we be able to give to our patients the best service.

Finally, a personal note. It seems that someone must be prepared to nail their colours to the mast, so here goes: (a) I deny the right of the Minister to prevent me from recourse to the courts of law. (b) I deny the right of the Minister to appoint my medical representatives on local, regional or central committees. (c) I deny the right of the Minister to direct me or anyone else either negatively or positively. (d) I deny the right of the Minister to abolish my ownership of goodwill in my practice. (e) I deny the right of the Minister to hold such dictatorial powers as he has under the Act, so that he can turn innocent men and women into criminals without proof of evil intent, and such powers that enable him to alter as and when he thinks fit all rules and regulations and financial arrangements by Order in Council. To join the Service while he has this power is futile even if all else appears to be conceded, as any agreements reached on regulations mean nothing and are valueless. (f) I deny the right of the Minister to withhold the annual report of the Central Health Council. (g) I deny the right of the Minister to confiscate property either of hospitals, nursing homes, or private individuals, because all these things mean the negation of freedom and democracy and will lead to a form of National Socialism very soon.

Therefore I will not join the Service until or unless these objectionable portions of the Act are repealed by an amending Act. I hope and pray that my colleagues who voted 'No' will do the same and those who voted 'Yes' will think again—I am, etc.,

Reading Berks

S F LOGAN DAHNE

SIR—The controversy between private practice as we have it now and State medicine as it is in process of being born goes on. May I put the point of view of a doctor who has had experience in many forms of medical practice? There are advantages and disadvantages in both 'private' and 'State' medicine and to rush enthusiastically but blindly into a new method or to cling unprogressively to an old method is asking for trouble. We want evolution and must have it, but revolution is fraught with dangers.

The new Health Act contains great possibilities for increased happiness to the people, and our own Association should use its influence in filling the framework with Regulations to form a measure of the utmost benefit. If each individual doctor eventually considers that his conscience will not allow him to work under the Act he can refuse, and it is his right to form an opinion both in regard to the ultimate good for the people and his own welfare. For after all the best work is done by the worker who is satisfied with his wage. We should surely see how the Act is going to work in practice, and give our help in making the Regulations before blindly refusing to have anything to do with a measure which has been passed by Parliament on behalf of the people—I am, etc.,

London NW 11

L STUART WOOLF

SIR—My statement 'We are citizens even before we are doctors' (Dec 7, 1946, p 874) meant simply that our civic duty—e.g., to obey the law of the land—is even more elemental than our medical duty, and the construction put on my words by Dr Alan Maberly (Dec 28, p 1002) is pure fantasy. His imputation of fanaticism, of inability to think clearly, to observe with detachment, or to foresee, to supporters of the Act is obviously bred of fear and mistrust of Socialism. How can he possibly know that Members of Parliament who passed the Act knew nothing of its ultimate implications?

I agree however, that 'this is a moral and ethical issue of the first importance,' and this is the issue. Shall the patient—the most important person concerned—choose the type of medical service he wants or shall the doctor impose on him the type of service he thinks he ought to have? Shall Parliament decide or the medical profession? Is it morally right to ask the patient to 'pay the piper' without allowing him to 'call the tune'? Drs D H Russell and J S Laurie (Dec 28, p 1002) respectively overstress and 'overr'

significance of the last sentence of my letter. It was obviously an afterthought with only an incidental bearing on the main argument—I am, etc.,

Wallasey

LENNOX JOHNSTON

A Medical Charter

SIR—In 1941, when this country was fighting for its life and for the destiny of mankind, our great leader, Mr Winston Churchill, together with the President of the United States, made an eight-point declaration of certain common principles of national policy. This declaration became known as the Atlantic Charter. It seems to me that our profession is passing through a somewhat similar period in its history and it might be equally opportune for it to declare now what are its fundamental ideals and principles. I would suggest that a professional charter should be drawn up which would embrace these and which could be understood by the public as a whole. Such a charter would have the support of the whole medical profession, and it would form the basis for examining, without prejudice, the National Health Service Act.

At present the profession is split into leaderless factions which show evidence of political bias in voicing their opinions upon the Act. Our profession should be above the political arena, and its attitude should be based on the principles of a charter and not on party politics. Let the brains of our profession get together now and put forward a charter which sets forth these ideals for which we will fight, and let only these be the means of deciding the terms under which we will serve.

I would suggest that the charter should include some of the following declarations:

(1) That the medical profession desires to serve the nation with the greatest possible efficiency and that it is agreed that some form of national health service is essential for the future welfare of our countrymen.

(2) That the profession expects the terms of service to allow full scope for its established ideals.

(3) That the service should give patients free choice of doctor and should be comprehensive. The profession recognizes the need for, preventing as well as curing disease, and in this it must be associated with the social services.

(4) That members of the service should be recruited voluntarily and that they should be free to practise their skill without fear of bureaucratic interference; that resources should be made available to them for this end.

(5) That the patient should receive primary consideration in all matters concerned in the setting up of the national medical service.

—I am, etc.,

Petersham Surrey

JOHN M JACKSON

The BMA and Mr Bevan

SIR,—The BMA should refuse to negotiate with Mr Bevan unless he first scraps the present Act, which is unacceptable to the profession and harmful to the best interests and welfare of the public, whose guardians in health matters we are. This Act was drawn up by the Minister to ensure that he, and he only, should enforce it as absolute dictator and executioner of any doctor who might incur his displeasure—and that without right of appeal.

We all know that our representatives were shamefully and contemptuously treated when they attempted to discuss the Act with him, and he had the bad taste to describe ours as a 'very corny profession' when addressing medical students a few months ago, many of whom, as sons of doctors, were well able to sum him up on that occasion. I say that Mr Bevan would not have formed this impression about our profession if he had not been guilty of attempting to trample roughshod over us and our patients' interests by means of the Bevan plan. The Minister has stated that because public money is to be used there must be public control, and that he abhors loading the young doctor with debt. I consider there is no justification for using public money in this way, and his statements are only political eyewash to cover the fact that we should become Civil Servants if we were to sign on the dotted line.

We will work a good Act but not a bad one, and this Act is a very bad one. No self-respecting doctor could bring himself to take service under it and become a cog in the State machine,

which would in time crush the life and initiative out of him. We have had enough warnings: the Willesden "closed shop," and the stoppage of essential foods for the dying by "remote control" from Whitehall overriding local specialists—truly a foretaste of things to come. So let us stand firm and demand that the Act as it stands be scrapped absolutely and a completely new one built up in consultation between the Minister and the medical profession, as it should have been in the first instance. If this is refused let us remember the Minister's statement that "no one is obliged to enter the Service unless he wishes," and stay outside. The general public are alarmed and daily ask us to stand firm and refuse to throw away our freedom to treat them in the best way—which would certainly not be under Mr Bevan's present scheme—I am, etc.,

Burton on Trent

J R SALMOND

The Presidents and Mr Bevan

SIR—The strategic letter of the Presidents of the English Colleges (Jan 11, p 66), in referring to the question of basic salary, contains the statement "There is general agreement that there are circumstances in which a basic salary or a guaranteed minimum may be necessary." Surely this difficulty could be dealt with by the grant of larger capitation fees for such areas. Once a basic salary is agreed to for any area it might be readily taken as a precedent and by Regulation imposed on other areas.

In the Minister's reply, referring to interference with liberty of movement of general practitioners, he states "There is a provision in the Act the sole object of which is to avoid an undue concentration of doctors in any one area. Clearly the more doctors are practising in any particular area the better for the public, as it gives greater freedom of choice. As to this question of liberty of movement on the part of general practitioners, it would be well for specialists to consider carefully whether eventually their own freedom in this respect may not be endangered, as it very definitely will be if they consent to payment on a salaried basis—I am, etc."

B H SHAW

The Appointed Day

SIR—When the flag of the National Health Service waves over our hospitals, when the last beauty queen has been kissed and the captains and the kings have departed, then perhaps the tumult and the shouting will begin. The principles upon which the BMA are taking their stand may be unexceptionable, but they have little application to hospitals staffs, whose interests are threatened in other ways. The word "strike" may be banned, but is there not some question of a possible back out? The flow of contributions and legacies to the voluntary hospitals has not been the result of charity acting in a vacuum: it has been stimulated by results, and the public have recognized and supported going concerns which have paid dividends in health and efficiency. Thus, over a fairly recent period of years, our hospitals have transmuted the skill and devotion of their staffs into bricks, plumbing, and equipment. The staffs however, in the process have lost control of these tools of their trade, so, on an "appointed day," these magnificently equipped factories may be closed to them except on terms which may not be acceptable. It would be interesting to know up to what point the Boards of Management and the British hospitals are prepared to defend the interests of their staffs, or will the keys be handed over unconditionally?

Has it been sufficiently realized that, on an 'appointed day,' the space-time factor will be suddenly altered? In many hospitals it would be impossible to find one vacant session for an extra clinic, or one vacant room. Staffs will have to be rapidly multiplied. Are the Royal Colleges prepared to accept the logic of the situation, and, without further delay to lower their examination standards in order to provide consultants? There is no evidence of this in the recent pass lists but the whole scheme may break down unless the men are ready at their posts.

The normal speed of working will be automatically reduced as the rapid and accurate, but almost intuitive clinical acumen resulting from experience is replaced by wholesale tests and documentation necessary to provide the Minister with material

at some question time' years hence X-ray plant and laboratory equipment will have to be found, elaborate filing systems installed, new wards built and equipped laundries enlarged, more porters stokers, clerks, stenographers, ward-maids, nurses—the list could be prolonged indefinitely. Is it possible on any appointed day" suddenly to establish a contractual obligation with the whole population of the country? Has any business ever been raised to this vast size by a stroke of the pen? It is a long time since Goethe said that such a feat would be impossible without turning the whole State into a nursing home. But the Minister knows better. He has a plan no doubt but can it be co-ordinated with all the other plans of all the other Ministries?

I suggest that we should now see this plan (if it exists) with all its details completed down to the last ward-maid. Time is short, and the public will soon be having their contributions deducted as in Germany they were deducted for the 'people's car'. The Minister has stated that it will take years for the Service he envisages to be in full working order. He has stated that he has a skeleton which must be clothed with flesh and blood. But whose flesh and blood, or is it our blood, sweat, and tears? And, in the meantime, what about the 'appointed day'? I suggest that the profession should adopt a helpful but waiting attitude emphasize its evolutionary principles, and neither by negotiation nor implication allow the Minister to 'pass the buck'. The 'appointed day' will be a Day of Judgment for somebody—let it not be ourselves—I am, etc.,

Bournemouth

T R AYNLEY

The Negotiators

SIR—I believe Dr Emid A Hughes (Jan 11, p 71) is right in thinking that members had not all the same reason for voting 'No'. My own chief reason was that I disagreed with the Negotiating Committee's points. I feel strongly that payment by capitation fee is a bad thing. This is partly because I shall personally suffer financially if it is adopted—my practice being completely non-panel pre-war and having dwindled while I was in the Army to what is called a 'nucleus' in the advertising columns—but it is also, and more, because I have had experience of practices with a maximum panel, where the proud boast of the principal has been how many patients he could dispose of in the hour, and the surgery has resembled nothing so much as the local fuel office. If private practice is practically abolished and the universal capitation fee instituted, we, who like to have time to examine our patients, shall be dragged willy-nilly into the competition for more and more numbers to the detriment both of our patients and of our own professional consciences—I am, etc.,

Bradford Yorks

KENNETH M M SHELDON

Paying the Doctor

SIR—Dr J Harris (Jan 11, p 71) says. I suggest, therefore that we should endeavour to persuade the minority not to accept service. How may I ask, is he going to persuade the minority not to join the new National Health Service? In the *Journal* some few weeks ago there was an advertisement for the F.R.C.S. (must be England) and the hospital concerned were offering the ridiculous salary of £250. When one sees many similar advertisements one realizes what one is up against. Now unless I mention it it will obviously be pointed out to me by someone that such a post carries a great deal of experience. This may be true, but once a medical student always a medical student. Why is it essential in gaining more experience to serve humanity to combine the experience with poverty? Any doctor however qualified deserves after one year's qualification to earn at least £500 per annum. Obviously a man with a higher qualification deserves more. The doctor should be well paid no matter where he offers his services—whether as an assistant in a hospital or in a laboratory or in any other post.

Unless and until the B.M.A. demand a minimum adequate salary to be paid to doctors then and only then will you get them to stick together. This is not my sole opinion but that of a number of colleagues who are in agreement with me. Therefore the B.M.A. must now act quickly and courageously

and fight for a decent salary, otherwise we have lost the fight, because the many doctors (with and without higher qualifications) who are poorly paid now are sure to join a Service which gives them a far better financial deal.

This has also applied to general practitioners in the past with their inadequate remuneration from the panel, etc. Therefore if the B.M.A. are prepared to face up to the truth and admit what is uppermost in most doctors' minds their only hope of unity is to see that doctors are adequately paid immediately—I am, etc.,

London N.W. 11

D V MORGAN JONES

The B.M.A. and Public Relations

SIR—Dr A Henry Gregson has to my mind made a most important point in his letter (Dec 21, 1946, p 961) under the above heading.

We have had in the main a bad Press. Because the voting on the plebiscite is so close we are described as a profession "split from top to bottom," etc., and all kinds of small unions burning with zeal for our welfare would take over the function of our own organization, and their statements, delivered with great weight and gravity, are given considerable publicity.

Little publicity has been given to the fact that our right of appeal to the courts in certain matters is being stripped from us. Yet so much could be made of this and its implications. The British working man, so aggressive in the defence of his own fixed hours and remuneration does not know that we still have no idea of our terms of service or pay in the Service into which we are to be "recruited." He thinks that this Act to a big extent is going to alleviate the lot of the doctor. If he knew these other things he might think differently.

We cannot stop this Act. To attempt to do so would be futile. The Bill has many good points, for ourselves and for the public, but it has as many ominous ones, and these it is our duty to fight.

Why should we not negotiate? Parliament passed this Act. We cannot dismiss the Government. If we refuse to negotiate we will be publicized as obstructionists, reactionaries, and capitalists of the worst kind. But if we do negotiate and the terms are dictatorial, then surely we can, in our just wrath, refuse to be enslaved.

I do not think then that we would lack the support of the population of whatever political creed they might be—I am, etc.,

Hull

WILLIAM GIBSON

A Foretaste of Control?

SIR—It is doubtless known to you that there are those who assert that the *British Medical Journal* is a poor journal because your columns never contain reports of important advances in our art and science. The number dated Jan 11 should make these malcontents hide their heads with shame, for you publish two reports of outstanding significance—one in the field of general medicine and one in that of medical practice. The former is, apparently, a discovery of those "eminent high-minded men, widely respected by their professional colleagues" (vide p 60), who act as medical advisers to the Minister of Food. These savants have informed Dr Foxell that "the [sic] pernicious anaemia is completely controllable by modern therapy and further that the achlorhydria can also be effectively treated."

It is of course, known to those experienced in these matters that most cases of pernicious anaemia can be controlled by proper treatment, but it is most emphatically untrue to assert that all can be. And, Sir, if there be, in fact, a successful treatment for the achlorhydria of pernicious anaemia, why are these 'high minded men' holding back the information? I find it easier to believe that they have said that which the Minister wished them to say.

The second advance that finds publication is that of Dr Wilfred Harris, who discusses (p 69) another of Dr Foxell's patients—the now famous one who died of carcinoma of the oesophagus. Of him Dr Harris says that as "the patient was suffering from inoperable cancer of the oesophagus and that he was bound to die shortly, I think most sane people would agree that it would be a serious waste of six persons' weekly fat ration for a very doubtful and temporary benefit."

CORRESPONDENCE

BRITISH
MEDICAL JOURNAL

Dr Harris does not go on to draw the obvious inference that is entailed by his statement—viz, that it would be a serious waste of rations to give this patient any at all, and even less does he go the whole logical hog and assert that the saving of food would be very great if all those suffering from incurable maladies were denied their rations. If Dr Harris's contention be accepted there is no logical stopping place before we draw the inference that we should not "waste" our substance on the incurable, the objectionable, the hereditarily inferior, and, of course, the racially unsatisfactory.

Sir, our duty as doctors is to our patients, but it may be that as they have, they are the less doctors, and not only that they have started down the slope, so easily descended, that ends in totalitarianism. The flower of our youth laid down its life for freedom and decency, the least we old buffers can do is to refrain from advocating the doctrines of their (and our) enemies—I am, etc.,

London W1

we give to the dying the less we give to the living. Is it then to be a principle that we feed the dying at the expense of the living?—I am, etc.,

Leeds

R A MURRAY SCOTT

**We regret that Dr Murray Scott appears to have missed the point of the leading article he so severely, if not melodramatically, criticizes—Ed BMJ

Curare

Sir—I should like to endorse the remarks of Dr Massey Dawkins (Jan 18, p 111) in respect of the use of curare. Although I am unable to cite the use of curare in a large series of cases, my experience of some of the after effects of curarization has already led me to express the opinion that curare is not without its dangers. Upon two occasions I have met the post-operative condition which Dr Massey Dawkins attributes to shock, in each case the operation, although abdominal, was neither extensive nor prolonged, and I do not think that shock could have ensued. My impression in each case was that the patient was in a condition of profound central depression resulting in prolonged unconsciousness and requiring active resuscitative measures. Neither patient received more than 15 mg of curare, each received 0.5 g of "pentothal," followed in one case by nitrous oxide, oxygen (30%), and minimal triline, in the other by light cyclopropane. Both were fit adults.

It seems that in some patients curare effects the cerebral synapses, that this action is prolonged and does not respond to physostigmine. I have not met paralytic ileus, but this seems analogous to the condition I have described and may well occur alone or in conjunction with the central depression I have met. This central depression appears to be unpredictable, it therefore behoves the anaesthetist to bear in mind the possibility of its occurrence and to make an early post-operative visit to those patients to whom he has administered curare—I am, etc.,

Bournemouth

S F DURRANS

Sir,—It is distressing to read the views of two of your correspondents in the *Journal* of Jan 11 (p 69) in letters arising out of the action of the Ministry of Food officials in refusing extra food to a dying patient of Dr Foxell's. One writer observes that as the patient was bound to die shortly most people would think that it would be a serious waste of six persons weekly with the preservation of the scheme and official forms. This outlook is contrary to established medical usage and Christian civilization. It is surely the ideal that the strong should sacrifice for the weak.

One hopes that this age will not become progressively utilitarian. There are many examples, both in the case of doctors and laymen, of lives being lost in an endeavour to save the dying.

Three small quotations from the last letters of Capt Scott, of Antarctic fame, seem appropriate. "Subsidiary reasons for our failure to return are due to sickness of different members of our party." "If this diary is found it will show how we stuck by dying companions and fought the thing out well to the end." "We have done everything possible, even to sacrificing ourselves in order to save sick companions. I think this makes an example for Englishmen of the future." Scott and his comrades gave their lives for the work, as have many others—an innumerable company. Officialdom appears to grudge a little butter for a dying patient. Is this the kind of attitude we are to expect under the national health scheme?—I am, etc.,

The University of Sheffield

ELIZABETH COWPER EAVES

Sir,—Dr Wilfred Harris's suggestion (Jan 11 p 69) that a man who is not expected to have much more of life should not be allowed some of the food which he needs is surely contrary to medical tradition and practice. Such a cruel decision could only be justified in a population where deaths from starvation were imminent.

Surely also is implied a great misjudgment of the sane and generous people of these islands. Millions would willingly give up a minute fraction of their fat ration, and many would give the whole, to comfort the last weeks of an afflicted man. Those who doubt the extent of such generosity must have failed in observation or memory even of the years of war—I am, etc.,

Birmingham

CRANSTON WALKER

Sir,—It would be impossible for anyone to disagree more thoroughly than I do with your melodramatic leader (Jan 11 p 60) with the above heading. You infer that when the country is short of some food, which has therefore to be equitably rationed, it is interfering with the doctor-patient relationship if that ration cannot be altered to suit each individual case. Surely, Sir, consideration of each individual case by Whitehall or a committee of experts would be chaotic and bureaucratic in the worst sense, and so to be avoided at all costs. Nor would it be feasible to allow doctors to order what they thought fit for the good of the individual when by so doing they might jeopardize the adequate supply of essential foods to the community. While food is in short supply the more

Sir—Dr Massey Dawkins's letter on this subject (Jan 18 p 111) cannot be allowed to pass without comment. Opinions whether based on the impressions of the nursing staff or on statistical results, as to the post operative effects of general anaesthesia alone, contrasted with general anaesthesia plus curare, are valueless unless the nature of the general anaesthetic is stated in each case. Assuming that Dr Dawkins is considering cases in which the general anaesthetic employed, with and without curare was the same it is still only too plain that he is comparing a well-given (say) cyclopropane alone with a badly given cyclopropane plus curare administration.

To take his three points in turn. First, the question of shock and "insufficient anaesthesia" surely the use of curare has at last invalidated the old theory, meticulously copied from textbook to textbook since it was propounded by Crile in 1920 that the fall of blood pressure during the effect of which could be minimized by deep anaesthesia (or better, the less toxic light anaesthesia, to ensure unconsciousness, plus curare) allows the surgeon to be as gentle as possible and thereby cause less trauma.

Secondly, "marked respiratory depression" may be caused post-operatively either by central depression as a result of relative overdosage with morphine and the more powerful anaesthetic drugs, or by muscular paralysis with curare. The first cause should not be effective if properly light anaesthesia is given with the curare and to eliminate the second correct dosage at the proper time is all that is required (last dose being given not less than fifteen minutes before the peritoneum is closed). If for some reason the operation finished more quickly, or the curare is eliminated more slowly than anticipated, then muscle tone is readily restored by intravenous administration of a suitable dose of prostigmine. Finally the factors predisposing towards post operative are (1) local, that is peritonitis whether traumatic, or bacterial and (2) central that is, broadly speaking, produced. The use of curare and the resultant relaxation of

Sulphathiazole

Sulphathiazole is one of the most active of the Sulphonamide drugs for the treatment of pneumococcal meningococcal gonococcal and haemolytic streptococcal infections. Many regard it as the sulphonamide of choice for the treatment of urinary tract infections.

May & Baker's sulphathiazole preparations are protected by British Patent No 533 495 which was granted on 24th May 1946 jointly to May & Baker Ltd and Ciba Ltd of Basle.

GUARDING THE ALKALI RESERVE

Maintaining the alkali reserve may call for alkalization beyond that which diet alone can provide. In such cases, as in febrile conditions and during sulphonamide medication the use of Alka-Zane will prove definitely helpful.

Composed of the four principal bases of the alkali reserve—sodium, potassium, calcium and magnesium—in the readily assimilable forms of carbonates, citrates and phosphates, Alka-Zane serves the dual purpose of alkalization and fluid intake. A teaspoonful of Alka-Zane in a glass of water or added to fruit juices or milk, makes a zestful, refreshing drink.

much to reduce the need for severe mechanical traumatization while it is the fact that ether and to a smaller degree the other claving inhalational anaesthetics are potent agents in predisposing towards ileus from the second cause. Here again the use of curare by permitting the administration of reduced quantities of inhalational intestinal depressants should lessen the chances of development of post operative ileus. The effect of curare itself on the gut was at first claimed in the U.S.A. to be parasympatheticomimetic. Workers in this country, possibly because of the greater purity of the product used, have been unable to confirm this but as far as I know nobody has yet considered it to have the reverse action and until some experimental evidence is produced that it does have any such adverse effect I see no reason why such a disadvantage should be imputed to it—I am etc.

Preston Lancs

A J GRAY

Curare or Magnesium Sulphate?

SIR—The danger of curare lies in the fact that relaxation of the muscles may be too extensive, it also appears that the action may continue and increase after the operation. It is surprising therefore that use is not made of a drug which gives relaxation to the same extent, and though it has the same possible danger of respiratory failure this can be countered immediately so also can its effect be annulled when the operation is over. I refer of course to injections of magnesium sulphate (0.5 to 1 ml of 25% solution). Its action is countered immediately by calcium salts, though I am not sure of the appropriate dose. In practice, then, it should be absolutely safe—I am, etc.

Kings Norton Thames

W F COOPER

Penicillin Pastilles

SIR—Dr G I C Ingram (Jan 4 p 31) discusses the possible causes of stomatitis following the use of penicillin pastilles. In the final paragraph of his letter he suggests that the base in which the penicillin is included may be of importance in the causation of this stomatitis.

In the original work by Long and myself on the use of penicillin pastilles in oral inflammatory conditions we made use of penicillin in a simple gelatin base to which only nipagin had been added as a preservative. The results that we published both in this Journal and in the *British Dental Journal* were obtained with this type of pastille, and we found that when fresh they were most effective. In over 600 patients who were treated with these pastilles we occasionally saw some discoloration of the tongue, but the stomatitis which occurs so frequently with the modern commercial pastilles did not apparently occur. The disadvantage of these gelatin pastilles was of course that owing to the comparatively high water content they did not remain stable for long periods and had to be made up frequently in fresh batches. We regard the base, however, as of considerable importance.

In a further publication on the spread of drugs in the oral cavity we showed that with a gelatin base the spread backwards along the mucous membrane appeared to be very much more efficient than when a solid and non glutinous base was employed. For this reason again therefore we advocated the use of gelatin as a base for the penicillin.

We have been most disappointed with the modern commercial pastilles. It is true that their keeping qualities are good, but in our experience they are not normally as effective as our original gelatin base type. We do not know the composition of the modern commercial types but we feel that the frequent appearance, which arises from their failure to achieve successful results, and the very numerous cases of stomatitis following their use that we have seen would appear to be due to the base employed. We would strongly advise those who have the facilities wherever possible to get their penicillin pastilles made up in a pure gelatin base according to the method that we originally described—I am etc.

ALEXANDER MACGREGOR.

Use of Penicillin Pastilles

SIR—Having some experience of the manufacture of troch penicillin B.P. may I be permitted to reply to Dr G I C Ingram's letter (Jan 4, p 31). Penicillin is rapidly destroyed in aqueous solution, and for this reason the B.P. requires the lozenge to be prepared dry by compression.

Stomatitis after oral penicillin may be due either to the penicillin or the sucrose base. This sucrose base involves a number of technical problems if the resultant lozenge is to be smooth and is to dissolve easily in the mouth but, having solved these problems and having used this method of preparation for a number of years and for a number of different lozenges, no instance of stomatitis from their use has come to our notice. In conclusion, may we have our terminology correct? Lozenges are prepared with a sugar base, pastilles with a gum or gelatin base—I am etc.

Ashton-under-Lyne Lancs

T H MANNERS KERFOOT

A Method of Giving Penicillin

SIR—Herewith we wish to offer you a summary of the preliminary report to the Society of Clinical Studies, Havana Cuba made at its session of Nov 14, 1946, referring to a new slow absorption method for penicillin injections. The method consists in mixing a penicillin solution with whole blood using as a solvent of the drug a solution of neutral sodium citrate (2%) and procaine (2.7%) in triple-distilled water. We (Machado Espinosa and Ramirez Corria) have used the following technique:

(1) We take 5 ml of the solvent and add to it the quantity of penicillin we wish to give in one injection—for instance, 500 000 or 600 000 units—shaking until the drug has been dissolved. (2) We then introduce the solution into a 10-ml syringe, preferably into a safety syringe (Luer-Lock). (3) With the syringe thus prepared we make a venous puncture in the patient who is to receive the injection, or in another person, and we extract a volume of blood equal to that of the solvent—i.e., 5 ml. (4) We shake the mixture in the syringe vigorously for not less than two minutes. If so desired the mixture of solvent, penicillin, and blood may also be introduced into an empty penicillin flask and be shaken there instead of in the syringe for two minutes.

(5) We now administer the total amount of the mixture in one deep intramuscular injection with an appropriate needle, preferably in the gluteus region. (6) The injections must be given at the rate of one injection every 24 hours, or according to the criterion of the physician. (7) The dose our experience has shown us to be optimal and which we recommend is one of 500 000 to 600 000 units for an adult weighing about 70 kg. For lower weights doses of 100 000 units for every 10 kg of body weight should be given.

We have been using crystalline penicillin, which in experiments with human volunteers, after injection in the above-mentioned amounts, has proved to be present in the blood at an exceptionally high concentration for adequate bacteriostasis as long as 48 hours after one injection—I am etc.

Havana Cuba

M MACHADO ESPINOSA

Behcet's Syndrome

SIR—I was interested in Dr E W Prosser Thomas's case (Jan 4 p 14) because thrombosis of the inferior vena cava occurred. Furthermore a section of the curious erythema-nodosum like lesion seen in these cases showed the pathology to be that of an acute inflammation and thrombosis of a vein. In one of the cases I reported in 1934 thrombosis of the deep veins of the thigh occurred. I do not think the ulcers of the genitals are always small and discrete. Some of the vulval ulcers are large, and repeated attacks cause considerable loss of vulval tissue. These genital ulcers also occur in the vagina and on the cervix, and can be of some size in these situations. Fortunately in the vast majority of cases the lesions are confined to the mouth, and aphthous ulcers in this site are of course exceedingly common. The syndrome can however, be very widespread and suggests multiple perivascular lesions because of this the syndrome falls into many specialized branches of medicine and its study suffers thereby. Some cases get no eye changes but I believe that many of the cases get acute ulcers of the stomach and that this accounts for the dyspepsia so often occurring with the mouth ulcers. If I

remember rightly, gastroscopy has been reported as confirming this supposition

In view of the utter uselessness of all treatment up till now any therapeutic measure would be welcome. The peculiar sensitivity of the skin would suggest a trial of "benadryl". This might be a valuable measure in those cases with eye lesions where any decrease of inflammation would mitigate the cumulative and recurrent damage to these organs—I am, etc.,

Oxford

G WHITWELL

Endocrine Receptors

SIR,—Mr Aleck Bourne's admirable survey of the endocrines in gynaecology (Jan 18, p 79) deserves high praise, and he is right in drawing attention to that neglected aspect of hormonal physiology, the reacting tissues, though whether the hypothesis of the "endocrine receptor" is necessary or not is another matter. That the question has not escaped the attention of all endocrinologists may be illustrated, for example, by the emphasis which H Zondek (*The Diseases of the Endocrine Glands* London, 1944) has placed on the importance of variability in the responsiveness of reacting tissues in bringing about some of the results observed in certain endocrinopathies. Cases such as that of Mr Aleck Bourne in which vaginal but not uterine responsiveness to oestrogens occurred are not so rare nor so exclusive as may be imagined, Zondek, for instance, describes a number of cases of undoubted Graves's disease which were accompanied by obesity, either generalized or localized, while the instances of localized gigantism and the very common occurrence of wide variations in the degree of development of different secondary sexual characters in individuals (males, perhaps, more than females) may also be cited as examples of localized hyper-reactivity or unresponsiveness of certain tissues to various hormones.

The variation in responsiveness of certain tissues to hormonal influences is, indeed a matter of everyday occurrence in the case of the alteration of sensitivity of the uterus during pregnancy to the oxytocic fraction of the posterior pituitary, and it is difficult to see here how the postulation of a receptor substance, or its presence in altered amount, can help to explain the observed phenomena. By all means, then, let due and increasing attention be paid to the question of the responsiveness of tissues to hormonal action, but let us at the same time avoid, as far as possible, complicating the already complex by the postulation of nebulous substances whose existence may well be impossible to prove—I am, etc.,

London NW 3

G I M SWYER

Endogenous Depression in General Practice

SIR—The letter (Jan 18, p 111) by Dr A Lionel Rowson should not, I think, pass without comment. Has he ever worked in a mental hospital? If so, it is difficult to understand the language of his first two paragraphs which is both diffuse and I submit inaccurate—certainly not helpful.

Dr Rowson does not take count of the constructive side of the problem. Patients are as a rule sent to mental hospitals because their relatives and/or their doctor have not the necessary facilities for adequate treatment. Nowadays the average mental hospital is staffed by intelligent medical officers who are keen on the curative side of their work, and in addition run clinics for out-patients to which the general practitioner brings or sends his patient for consultation. Moreover, in the hospital itself much use is now being made of many modern methods of treatment. I would mention electroconvulsion therapy as an example. It is not quite clear what Dr Rowson means by endogenous depression—i.e. whether manic depressive psychosis or anxiety neurosis. ECT cures a large number of the former, and the consultative clinic of the latter. But they are quite different conditions.

Everyone who has worked in the larger mental hospitals would welcome improvements such as smaller wards and more female staff for the chronic cases, but those patients with acute depression are nowadays customarily treated in the admission or "acute" wards which are well equipped both for diagnosis and therapy. For those who can afford a moderate inclusive charge a private institution is often very suitable for

cases of anxiety neurosis. I have myself worked in both types. Additional facilities for the cure of depressed cases are to be found in occupation therapy and the services of a good hospital chaplain—I am, etc.,

Protein Requirements of Adults

SIR—With reference to the leading article on the above subject (Jan 4, p 19) I should like to point out that all protein requirement values based on balances are quite unreliable. Everything being equal, the requirement varies in inverse ratio to the length of the period during which the subject has become used to a low protein intake. With a protein intake which even for three months may give a negative balance, if the experiment is continued long enough, an equilibrium is frequently obtained. It is quite impossible to say what the minimum protein requirement is. Moreover, it varies considerably from individual to individual, depending as it does on the function of the thyroid, etc. (*High Blood Pressure* 1937).

In the treatment of high blood pressure we found it was desirable to obtain requirement values for each individual. But it is not generally realized that the availability of other substances, such as a large intake of inorganic bases, influences protein requirement (Harris, I, Ireland, J T, and James, G V, *J Physiol* 1941, 99, 370). Apparently the substances which are available in large quantities are more readily utilized. This has the force of a physiological law (Harris, I *et al*, *Studies in Hypertony and Prevention of Disease*, 1946). Requirement value of protein not only depends on the protein intake but on the availability of other substances. Balances are clearly no evidence at all of requirement. The minimum protein requirement is unknown, and it is difficult to discover what the optimum protein requirement is. It is equally possible to obtain an equilibrium on a 25-grammes-of-nitrogen intake and on a 5-grammes intake per day. The question arises, Which represents the optimum requirement? We do not know. The only way to find out the optimum requirement of protein and of many other substances is by prolonged clinical observation. A number of high blood pressure cases on low protein have been under my observation for some time, and at the Institute of Research for the Prevention of Disease a number of normal cases are kept on low protein diet, and from time to time their intake of nitrogen is checked by the determination of urinary nitrogen. Only in this way will it be ultimately possible to find out which is the optimum protein requirement. It would be very valuable if all workers interested in the subject would co-operate in this most valuable experiment, pooling resources, for it is necessary to have a very large number of cases under observation for a very long period before a definite conclusion can be arrived at—I am, etc.

Liverpool

I HARRIS

Secondary Abdominal Pregnancy

SIR—An account of a case of this rare condition may be of interest.

CASE REPORT

The patient was a Bantu woman aged about 25 or 30. She stated that her husband had had syphilis, untreated except by native medicine, and that of her three children the first was stillborn, the second died at the age of 5 months, and the third died at 2 years. The causes of death were unknown—presumably syphilis.

She was admitted here at full term on June 15, 1946, and antisyphilitic treatment was begun. The abdomen was the size of a nine months pregnancy and the child lying as a breech presentation. No abnormality was suspected at this time. On June 25 of ricin and an enema were given to try to induce labour, and this was repeated the next day and on July 4. On June 30 the child was found to be lying transversely, it was turned to a breech presentation and a binder applied. On July 2 the presentation was difficult to define, the limbs were felt near the umbilicus. For the next three days the woman had intermittently what appeared to be labour pains but on vaginal examination there was no "show" and no dilatation of the cervix which was noted to be firmer than usual for full term pregnancy. The presenting part could not be clearly felt. On July 5 the "labour pains" began again, and the patient's general condition began to deteriorate. To our surprise she not only consented to operation but asked for it. The women here are often reluctant to undergo operation.

The abdomen was opened by a median incision. The incision of the peritoneum also opened the child's sac, and at once rather foul-smelling yellowish fluid escaped and the child's foot presented. The child was lying transversely, it was alive. The placenta was thin and friable and its edges difficult to define. As much as possible was removed. There was surprisingly little haemorrhage. On exploring the abdomen it was found that the uterus enlarged to the size of a three months pregnancy, was lying towards the left iliac fossa and that the tube and ovary of the left side were normal. The right tube and ovary could not be found. The child had been lying in a thin walled sac, apparently of peritoneum whose attachments were to the right side of the pelvis and right iliac fossa. The placental connexions were entirely within this sac. There were no adhesions at all to bowel but a few tags of membranous exudate were on the abdominal surface of the sac. There was no connexion between the uterus and the sac the thinnest part of which was excised and the gap sutured. The abdomen was closed without drainage. At the end of the operation a large dilator was passed through the cervix, and on the day after the operation there was very slight blood staining of a vulval pad but no other discharge at any time before or after operation.

The child had no obvious abnormalities: it cried well and took fluids the first day, but died on the second day. No post-mortem examination was possible.

A report (for which I am indebted to the Pathology Department of Witwatersrand University of Johannesburg) states: 'The section showed no sign of tubal tissue. There was a large amount of blood clot and chorionic villi pregnancy. From the sections it is difficult to determine whether pregnancy was tubal or intraligamentous. On questioning the woman afterwards I tried to find if there had been any symptoms of tubal pregnancy in the early months, but could get no clear history from her. She made a good recovery and the wound healed well in spite of her being found sitting on a bed pan on the floor on her first post-operative day and having an epileptic fit on the third day.'

The probability in this case is that there had been a tubal pregnancy followed by intraligamentous rupture of the tube with the survival of the membranes as the sac appeared to consist of broad ligament and there were no placental adhesions to bowel. Unusual features of the case are that the child was alive after three days "spurious labour" and that there was no decidua cast or other discharge from the uterus—I am etc.

R. GWYN DABB

Trilene in Labour

SIR—Trilene has been recommended as a suitable anaesthetic for women in labour. No one will deny that it can be dangerous and there is evidence that it delays coagulation time, affects the conduction in the heart and may damage the nervous system and liver. When it is used as an analgesic in normal labour the risk is probably small but until a sufficiently large series of cases has been observed and recorded its safety should not be taken for granted.

As an anaesthetic for instrumental delivery it is doubtful if it has any advantages over other available means and it appears to be definitely dangerous for caesarean section. It was used in 82 cases in a continuous series of 272 caesarean sections during 7 years and 9 months to September 1946. Five of the mothers who received trilene collapsed and died within 6 days of the operation. Neither the clinical condition of the patient nor post-mortem examination revealed any cause for the death. Only one death occurred among the 190 cases not receiving trilene. In the absence of further evidence trilene should never be employed for caesarean section—I am etc.

D. M. STERN

Rubella and Pregnancy

SIR—I venture to send you a personal experience on this subject and propose of your leading article (p. 778 No. 23 1946). I have a second daughter aged 6 years who is a deaf-mute. Her mother (my daughter-in-law) had German measles in the third month of her pregnancy.

An excellent little school was found at Cuckfield in Sussex, in which there are 15 deaf-mute children—all the same age and all apparently victims of an epidemic of German measles which occurred in 1940. In 17 out of the 15 children there is a defi-

nite history of the mother having had German measles in the early months of the pregnancy.

This is strong evidence on the question of aetiology. The occurrence of deaf-mutism is such a domestic catastrophe and permanent sorrow that I advocate inducing abortion, as I understand is being done in Australia. But I am in my ninety-second year and unable to take active steps in any cause, I therefore hope that you can—I am, etc.

ROBERT SANDERSON

Surgical Aspects of Roundworm Disease

SIR—The interesting article on "Surgical Aspects of Roundworm Disease" by Capt F. Barber (Jan 11, p. 49) prompts me to make a few comments. In West China we have also been impressed by the great variety of symptoms produced by roundworm infestation. I have no clinical records of these cases with me and so can only write from memory.

A Chinese girl of about 16 had attacks of very severe abdominal colic, a tentative diagnosis was made of intestinal volvulus and strangulation—we had seen a case recently that proved to be that at operation. At laparotomy of this girl the small intestine was found to be a mass of knotted worms. The abdomen was closed, the patient was treated with anthelmintics and made an uninterrupted recovery.

Another case was a European boy of about 4. He was not well for 1-2 days, ova of the roundworm were found in the faeces and he was treated with santonin. Next day the condition did not improve but developed into a more typical case of appendicitis with local signs. At operation the appendix was removed, it was definitely inflamed and there was a roundworm occupying the whole length of the lumen. The sequence of events in this second case is very much open to discussion. Was it appendicitis in the first place? Or did the santonin cause the worm to take refuge in the appendix and secondarily set up inflammation in that organ?

I would like to add a few comments on treatment. In the type of case illustrated by the first case above and Capt Barber's Case 1, I wonder why he recommends removal of the worms surgically. Capt Barber says: "Medical anthelmintic measures are not advisable for at least two weeks after incision and suture of the gut." This seems to me a contraindication to taking the unnecessary risk of opening the gut. Most of these cases are children who have a general anaesthetic which itself is an anthelmintic and some worms are subsequently passed and vomited when the gut has not been opened. Ordinary anthelmintic measures can be instituted 2-3 days after operation. At laparotomy for other conditions I have not infrequently seen knots of worms in the intestines but have never removed them surgically.

In the type of case illustrated by Capt Barber's Case 2 I would favour laparotomy if there is serious question of appendicitis, the danger of delay and purgatives especially in children is a real one. I can remember three Chinese children whom I lost with perforated appendicitis, one of whom had orthodox Western treatment for worms the day before I saw it and the other two had had a few days' treatment with Chinese medicine, which was probably herbal anthelmintics and purges. I should add that these three certainly had worms—I found them loose in the abdomen—I am, etc.

F. CHRISTOPHER MADDON

Osteomyelitis of the Spine

SIR—Articles have recently appeared in the *Journal* by Mr Harry Freeman (Oct 26, 1946 p. 610) and Mr Peter Martin (Nov 9, 1946, p. 688) dealing with pyogenic osteomyelitis of the spine. May I be permitted to draw attention to a case which I described in detail in 1935 (*J. Bone Jt. Surg.* 1935 17 468) as having some interest in connexion with this condition?

A female patient aged 20 was admitted to the Royal Sea Bathing Hospital for surgical tuberculosis on Aug. 22, 1932, with a chronic osteomyelitis of the lower third of the right femur. While awaiting an operation for saucerization and skin grafting of the diseased area in the femur (after the method devised by Dr Basil Arlidge, medical superintendent of the hospital) she developed a spastic paraplegia which was complete—with involuntary spastic muscle contractions occurring in flexion, complete loss of sensory perception up to the fifth rib, and loss of control over micturition—by October 1932. A ray of the spine revealed no abnormality.

X-ray examination following injection of 'lipiodol' into the anterior margin and into the lumbar region of the subarachnoid space with inversion of the patient revealed an extramedullary block extending from the body of the second thoracic vertebra to the lower border of the fourth. Laminectomy was contemplated, but by Nov 10 slight objective sense perception was demonstrated and some control over micturition was evident. Steady improvement occurred and normal function and normal signs in both lower limbs were established by May 15, 1933.

On July 12, 1933, an abscess made itself evident at the vertebral border of the right scapula. This was incised, and the subsequent sinus healed in six weeks. A pure culture of *Staph. albus* was grown from the abscess pus. There were no signs or symptoms referable to the back prior to the development of the abscess. Examination as an out-patient in May, 1934, showed the femoral lesions to be completely healed and epithelialized, and the spine and back seemed perfectly normal.

It remains a matter of speculation whether the above sequence of events was due to a metastatic abscess unrelated to a focus of bone infection, or whether the abscess developed secondarily to a 'minimal' bone lesion too small to be detected by X-ray examination, as occurred in Case 1 of Mr Martin's series (Nov 9, 1946, p 688)—I am, etc.

Cleveland Ohio U.S.A.

T FRANCIS JARMAN

Air Crashes and Fractured Spines

SIR—The development of civilian flying seems to be causing an increase in the number of fractured spines, and their treatment may now have to be undertaken by those inexperienced in the application of hyperextension plasters. Serious sores may be easily caused, and yet they can almost always be avoided if the two following precautions are taken.

(1) A strip of adhesive felt 6 in (15 cm) wide and about 36 in (0.9 m) long is fixed down the centre of the back over the spinous processes and smaller strips of the same material cover the iliac crests, symphysis, and umbilicus. Stockinette or an old bathing costume may be put over this, but no cotton-wool should ever be used.

(2) The first plaster of Paris applied to the back of the hyperextended patient must be a 6 in longitudinal slab from the base of the neck to the sacrum. This is held in place by circular 6 in plaster bandages, supplemented of course by additional slabs and in particular by the all-important anterior strut, which takes its bearing on the umbilicus, sternum and symphysis pubis. The common mistake is to start with circular bandages round the lumbar region (which is of course in marked lordosis), with the result that they tend to slip down into the lowest part of the hollow of the back and make a sharp transverse ridge which can and does cause disastrous plaster sores.

Every orthopaedic and fracture department has of course the necessary equipment, but it is my firm belief that even the smaller hospitals should always have a stock of 6 in plaster bandages and adhesive felt—I am, etc.

ERIC I LLOYD

Eye Surgery

SIR,—It is not my desire to counter any criticism in your review of my book *Eye Surgery* (Dec 28 1946 p 989) but I feel unable to allow your reviewer's statement about Kronlein's operation to pass unchallenged, for if this is accepted by your readers it will give a wrong impression of a valuable operation. The comment in your review is thus:

Few surgeons who have tried it will agree that a Kronlein's operation is particularly valuable for the removal of retro-ocular new formations." All the cases which I have done of Kronlein's operation for an orbital neoplasm have recovered visual acuity in some instances from perception of light to 6/6 (partly), and the visual field has improved very appreciably. In two of these cases orbital exenteration had been advised by more than one surgeon. In one case transfrontal craniotomy had been done at Oxford where the report was that "the orbital neoplasm was not seen." Nine months later I removed it by Kronlein's operation: the patient was spared exenteration, the optic nerve which was stretched over the neoplasm recovered almost entirely, save for a small defect in the visual field.

Another point made in the review concerns the use of two needles for dividing thick capsule remnants. The reviewer writes "Whether one needle bent at an angle should be used

in operations with two needles seems a moot point. Most surgeons prefer to avoid angled instruments since direction is less certain than with straight instruments." He will have read earlier in the book my comments about straight instruments making precision work easier than is the case with angled instruments. The latter are, however, necessary in entering the eye from the nasal side, as in capsulotomy with two needles and in using a keratome on a deep set eye with prominent supra-orbital margin. It is quite impossible to use anything but an angled instrument under these circumstances, the nose and brow forming obstacles.

Another comment which I think is likely to mislead is "The author likewise probably takes an extreme view in believing that malignant melanoma of the choroid are not so radiosensitive as glioma of the retina." Although I have had success in irradiating malignant melanoma of the choroid with radon seeds sutured to the sclera, it is a fact that these neoplasms are not so radiosensitive as glioma of the retina.

I express my grateful thanks and appreciation of your reviewer's generous remarks elsewhere in his review—I am, etc.

London W 1

H B STALLARD

Defective Colour Vision in Industry

SIR—In the opening sentence of the leading article (Dec 21 1946 p 948) you make an excellent point when you say "Defective colour vision, more commonly and less accurately called colour blindness." That you should emphasize the frequency of terminological inexactitude in this connexion is of great importance at the present time when the role of colour vision in industry is receiving greater attention. So many of the so-called anomalous trichromats declare most emphatically that they are not colour-blind, and their contention is undoubtedly correct. The explanation of the defect as a faulty colour appreciation is well received, and now is the time to urge very strongly that the term colour blind should be replaced by the term colour-defective.

The time is also opportune to suggest that the presence of defective colour vision is only in a limited number of cases a bar to the efficient performance of many of the tasks mentioned in your article. As is well known, the R.A.F. had many colour-defectives who as members of aircrew played an important role in all commands, and the salvage of manpower achieved by the use of the colour-defective safe category was considerable. This "safe" category has, however, been subjected to much criticism—perhaps the most important being that the personal equation of the examiner was too great. During the war much work was done in this country and in America to work out the permissible degree of colour defect for certain tasks. Clearly there is a great field for the salvage of colour-defectives in industry just as in the Services but it is now realized by all who have been asked to do colour vision testing on a large scale that the problem is exceedingly complex and admits of no easy solution. Difficult borderline cases will always appear.

Later in the article you are on less sure ground when you state that the mothers of male colour defectives are not themselves affected. It is probably true to say that these relatives are not so grossly affected, but by more accurate testing methods—anomalousoscope or colorimeter—quite a number of these women show a definite deviation from normal. Pickford has investigated this problem and he found among the female relatives of colour defectives a considerably higher incidence of colour defects than the expected. I have seen one or two families where the sister of colour defective brothers has had a marked degree of colour defect—I am, etc.

Diet and Canine Hysteria

SIR—As a member of the sister profession may I be allowed the courtesy of the use of your columns to comment upon the report (Dec 14 1946 p 885) of Sir Edward Mellanby's feeding experiments? This piece of work has aroused lively interest in the veterinary world and we would all most heartily welcome a final elucidation of the aetiology of canine hysteria.

While of course according the greatest respect to the work of so eminent a scientist as Sir Edward, I feel, as a clinician, that his findings do not quite fit in with all the known facts concerning hysteria as it occurs in the field. In the first place Sir Edward stresses the occurrence of epileptiform fits among the symptoms, unconsciousness lasting sometimes half an hour up to 36 hours, yet I must say at once that such fits are not a prominent feature of canine hysteria in the field. Is the condition produced by Mellanby that which a veterinary surgeon recognizes clinically as hysteria, or is it some other condition?

I personally have always held that canine hysteria had an alimentary aetiology and I favoured a toxic rather than a deficiency factor. The recent experiments appear to confirm the first belief and incriminate treated wheat flour as the actual cause. It is alleged that dogs fed on a diet containing agenzized flour will contract hysteria while control animals fed on the same diet but with the cereal portion not agenzized will not do so. It is said that 90% of the flour consumed in the country is agenzized and it is scarcely conceivable that animals, whether consuming bread or biscuits can avoid consuming agenzized flour. The racing greyhound, of which there are many thousands is normally fed (in times of abundance) upon stale bread soaked in gravy, mixed of course, with other foodstuffs. The majority of this must have been agenzized.

It is pertinent therefore to ask why all these animals up and down the country have not been in a perpetual state of hysteria. Yet the occurrence of hysteria is comparatively rare and very sporadic. Can it be contended that an immunity is acquired from the consumption of bread? If so, why are only some and not all immunized? It is certainly true that recurrence in the same animal is most unusual.

It has been my experience, and that of many others, not excluding Sir Edward that to change the food or its source has been practically all that was needed to abort an outbreak in a kennel or stop an attack in an individual. This must have meant in innumerable cases changing from one make of bread or biscuit to another make in effect to feed on food made from an entirely different consignment of flour. This led to my strong belief that the aetiological factor was possibly a parasite of wheat or a mould on the stale bread, especially as Russell Greig had proved (in 1922) that what he then called epileptiform convulsions could arise from the presence in the alimentary tract of a wheat parasite—*Tilletia tritici* (hunt or stinking smut). Such a theory is not yet disproved.

Although it is claimed that the real incidence of hysteria occurred at about the same time as the introduction of the agenz process yet there are in the literature references to hysteria made earlier than this, and I have known of the disease almost as long as I have been in practice—now 35 years. It is open to doubt if hysteria has really increased from the very early days when it was first reported since it may only be that the diagnosis has been more complete. In the kennel of some 300 greyhounds over which I have veterinary control I have not had to report a single case of hysteria for more than a year. The last attack—in about half a dozen dogs—occurred about two years ago. I have seen about seven cases in private practice during the past year. In the meantime I am making inquiries in other countries which may throw light on the subject. It would be enlightening to know the total number of dogs employed in Mellanby's experiments and what was the actual percentage which contracted hysteria.

There are other issues too which could be raised if space would permit. Anxiety has been expressed in the lay Press and elsewhere that humans should be obliged to consume food which is proved to be unsafe for dogs. Is it assumed that such food would produce hysteria or epileptiform fits in man? So far as I am aware there seems as yet little evidence that the general health of mankind has suffered in consequence of the fact that I am not aware that either of the above conditions has been produced in man—I am, etc.

HAMILTON KIRK

Mental Deficiency

SIR—Dr Mary M. Paulin (Jan 4 p 31) in drawing attention to the case of a man under the Mental Deficiency Act (Dec 14 1946 p 929) herself states that she had hoped that, by this time, some one else would have drawn attention to the case, but as they seem to be likely to be passed unheeded I feel I must do so as failure to

realize their significance may cause distress to many parents. The question is somewhat complicated so that for the sake of brevity I shall mention only the main points. Dr Paulin states that the Education Act of 1944 gives to local authorities the power to order special educational treatment for mentally deficient children. [The italics are mine.] It should be noted that the phrase "mentally deficient" has been abolished from the educational world by the Act and should not be applied to educable children. Those who are backward but educable are now known as educationally subnormal.

Referring to the original question (Dec 14, 1946), I have difficulty in understanding it. If the child is an "idiot" as stated in the question he is ineducable. The local education authority cannot send him to a special school. It is their clear duty to refer him to the local (mental deficiency) authority. If he is educable he is certainly not an "idiot" (An idiot is a person who is unable to guard himself against common physical dangers). Referring to your answer (Dec 14, 1946) I again find a difficulty. If a child is certified as a mental defective under the Mental Deficiency Acts of 1913 and 1927 he is beyond the jurisdiction of the local education authority and cannot be sent to a school ordinary or special. The local (mental deficiency) authority can send him to an institution at the instance of the parent or guardian or under certain other conditions such as neglect.

If the word "idiot" is used inadvertently in the question and should be replaced by the words "educationally subnormal" then it is the duty of the local education authority to provide special treatment in an ordinary school or, if they think desirable, in a day or residential special school (unless the parent makes other suitable arrangements). If the child is ineducable it would be not only illegal but also most undesirable in the interests of other children to allow him to attend school. If he is educationally subnormal it is essential that he should have appropriate educational treatment, and, if the backwardness is very marked, it is unlikely, as is suggested in your answer, that such education could be provided in a village school.

The Education Act of 1944 allows for appeal by the parent to the Minister of Education against the decision for special educational treatment or for reference to the local (mental deficiency) authority. It should be realized that in this and various other ways the interests of the child and the rights and feelings of the parents are very carefully protected by the Acts. Various circulars issued by the Ministry have emphasized this. For the educable there is in many areas a shortage of accommodation in day special schools, and throughout the country there is very serious lack of accommodation of residential special schools, and for the ineducable there is gross lack of institutional accommodation. Hence it is in only very clear-cut cases that an educational authority is likely to want to send an educable child to a special school or a local (M.D.) authority to want to send an ineducable child to an institution—I am, etc.

Nottingham

A. A. E. NEWTH

Age Limit in Advertisements

SIR—I was interested to read the letter from Dunmar (Dec 28 1946 p 1007) on the age limit for whole-time posts under the various ministries. There appeared a short time ago an advertisement for a regional medical officer under the N.H.I. Having reached the ripe old age of 50 in March I found I was six months too old for it. The fact that I was too old was due entirely to the four years I spent in the Army 1914 to 1918 before beginning my medical training. I was then, in common with thousands of others, labouring under the delusion that in fighting for my country I was more fitly serving it.

In the 1920s a similar post was advertised for Scotland the age limit then being 35 again debarring ex-Service men. Last year there was a vacancy in Scotland again the age limit being raised to 45. This still excludes men like me, but also proves that the age limit is capable of adjustment.

I sent for an application form for the posts advertised in November and was much interested to read that not only did my old age count against me but the disgrace of never having been captain of the school never having been even a prefect had put me beyond the pale. I received my early education among the very men who are patients under the N.H.I., and

presumably should know them. Alas, no old school tie was ever issued or thought of, and in the few intervals between having the fear of God and the love of the three Rs drilled into us, we kicked a ball about the playground and imagined this Sport. Now although I have over 20 years' experience of working the NHI Act, I am evidently unfit, thanks to my war service and my background, to apply for posts where knowledge of and experience with the worker is so desirable. I am sending a copy of this letter to the Minister of Health for his consideration—I am, etc.,

BLACK WATCH

Future of the Colonial Medical Service

SIR—The Report of the Harragin Commission to West Africa on proposed revision of salaries has done nothing but cause further discontent, and if put into effect will seriously influence recruitment and, perhaps, lead to many resignations from serving members, particularly those who are at the beginning of their career. I wonder if those members of the profession who intend to answer the 'Utopian advertisement' inserted in the *Journal* and perhaps join the Service, really know how the salary offered to doctors compares with that of other members in the Colonial Service. Would they join if they knew that, for instance, a cadet in the Administrative Service, average age 21 to 23, is to be offered £535 per annum and makes just on £100 per annum in allowances, bringing his total income to £635 per annum? The proposed salary for the medical officer is £680 per annum—and without the possibility of private practice, which it is proposed to abolish, or the opportunity of claiming allowances. This amounts to downgrading the status of the doctors, because cadets are to have their initial salary increased by £135 and the doctors by £20. The cadet has no qualifications or expensive training, only undergoing a short "Colonial course" at the university, and commences to earn his pension when he joins at the age of, say, 23. Compare this with the doctor who has five years' training and two years' earning little money (house appointments and DTM and H course) and joins at the average age of 27 thereby 'losing' four years on his pension as compared with the cadet.

If you knew that a layman four years younger than yourself, who had no special qualification for his job, was earning only £45 less, would you accept the post on the salary offered? If £850 per annum were the salary offered I think there would be little cause to complain. Furthermore, while nearly all other departments have had an increase in the region of £200 on their maximum, the medical officers' maximum remains the same (£1,200) while senior medical officers have a miserly increase of £35. Further downgrading of the status of the profession is shown by the fact that nursing sisters, who must possess both SRN and CMB, are to be graded below secretary-typists.

The fact that Africans' salaries have been raised, although disguised as a cost-of-living award—and it is proposed to increase them still further—is too preposterous to comment upon. For those who think of entering the Service it is as well for them to consider the above facts in relation to the apparently rosy prospects offered in the advertisement—I am, etc.,

DISILLUSIONED

History of Arab Medicine

SIR—Permit me to make the following comments in reply to a statement made in a letter by the late Dr A. R. Neligan (Dec 14 1946 p 919). Dr Neligan writes 'The Arabs avid of knowledge and industrious translators of Greek medical and other texts, produced few physicians of note. Arabian medicine was largely the work of Persians, Jews, and Syrians.' This statement is as misleading as it is incorrect, and reveals little familiarity with the history of medicine in general and the history of Arab medicine in particular, as recorded by Arab historians (in Arabic) and other western scholars of Arab and Islamic culture of the period in question. However, it is impossible here to more than just point out a few features of major Arab contributions to the sciences and medicine. From the standpoint of history "transmission is no less important

and essential than origination, and the line between both is often hypothetical'. In the words of the eminent scholar Prof P. Hitti, 'Had the researches of Aristotle, Galen, and Ptolemy been lost to posterity the world would have been as poor as if they had never been produced'.

The Arabs are the people of the Arab, and later Islamic, Empire, of which Persia—the fertile crescent—Egypt, and later Spain formed part, and in which the Arabians were the inhabitants of the peninsula. Arab civilization embraced the Arabian, with which it was connected by linguistic and later to a lesser degree, by religious ties and throughout the period of the Caliphate the Arabs (Arabians, Syrians, Persians, Egyptians, and others, Moslems, Christians, or Jews) were the foremost bearers of the torch of enlightenment and learning (with special stress on the humanities), and in Arab-Islamic civilization as such the cultural unity of the Mediterranean basin found its final culmination. As a result the world remains indebted to the legion of Arab stars in the firmament of science, culture, and medicine, of which Al Razi and Ibn Sina were two. As late as the 14th century Christians stood helpless before the 'black death' then ravaging Europe, and considered it an act of God. However, the Arab Moslem physician Ibn Al Khatib, of Granada, held that infection and contagion spread the disease, and thus anticipated Pasteur by five centuries. Here is a passage of his treatise 'To those who say, 'How can we admit the possibility of infection while the religious law denies it?' we reply that the existence of contagion is established by experience, investigation, and the evidence of the senses, and trustworthy reports. These facts constitute a sound argument. The fact of infection becomes clear to the investigator who notices how he who establishes contact with the afflicted gets the disease, whereas he who is not in contact remains safe, and how transmission is effected through garments, vessels, and savings'. This could have been written only yesterday, except that when made such heretical statements in Europe might have brought on the vengeance of the Church and perhaps cost the life of such a heretic.

May I mention one or two names that stand apart as great beacons in medical history? First, the Arab surgeon Abu Al Quasim Al Zahrawi (fl 1013) who in his voluminous works summarized the surgical knowledge of the period and introduced new ideas—as the treatment of wounds by cautery, the crushing of stones inside the bladder, and the necessity of vivisection and dissection. His illustrations of instruments influenced Arab doctors and helped lay the foundation of surgery in Europe. Secondly, Ibn Zuhr (1091–1162), of Seville, was as outstanding in medicine as Abu Al Quasim Al Zahrawi was in surgery, both being prolific writers. Ibn Rushd, writing of him, says, 'Ibn Zuhr is the greatest physician since Galen and the greatest clinician since Al Razi'. He was the first to discuss feeling in bones and to describe the itch-mite scabies (*jarab*), though Al Tabari (10th century) anticipated him in its discovery.

The list of great names is too long. I would conclude by pointing out that a perusal of medical history would disprove any such statements as those made by Dr Neligan, and a little study of the subject in review would be amply rewarding both in revelation and interest—I am, etc.,

Jerusalem

I B GEORGE

The twenty-third annual report of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation records that during 1946, the year covered by the report, grants were made to twenty institutions and investigators to aid research. Grants are given in the sciences closely related to medicine, without reference to special fields and to the end of 1946 the Foundation had distributed 551 to scientists throughout the world. Applications for grants to be held during 1947–8, which must reach Dr Joseph C. Aub, Massachusetts General Hospital, Fruit Street, Boston, 14 Massachusetts, U.S.A., by the beginning of April, must state the qualifications of the investigator, give an accurate description of the research, state the amount of grant requested and describe the specific use to which the money will be put. Applicants should also state whether or not they have approached other foundations for financial assistance and what other sources of support are relied on for research. Letters of recommendation from directors of the departments in which the work is to be done should be included if possible.

Obituary

Dr CHARLES WILLWOOD RUBIDGE died at his home in Graaff-Reinet, Cape Province, South Africa, on Dec 8, 1946, at the age of 52. Dr Rubidge was the only son of Dr John I. Rubidge, who started the first medical practice in Murrumbidgee. Dr Charles Rubidge began his education at Selbourne College, East London, where his father was then in practice. Later he joined the first batch of students at the Grootfontein Agricultural College in 1910. He completed a two-year course and took over a farm just north of Graaff-Reinet. Then the outbreak of the first world war prompted an appeal for more medical men. Dr Rubidge responded by entering Edinburgh University with his sister. He qualified M.B. Ch.B. in 1920. Returning to South Africa, he married Dr Anne Macdonald, a fellow student at Edinburgh, and for the next twelve years they carried on a large practice at Willowmore. Unfortunately, Dr Rubidge's health was not good, and so in 1932 he left Willowmore for a much less strenuous life in practice at Graaff-Reinet. His wife died some six years ago, and Dr Rubidge, whose death is a great loss to the profession in South Africa, is survived by his father and by his sister, Dr Louie Rubidge, who practises in Salisbury, Rhodesia.

DAVID JOHNSON SCOTT, who died on Dec 9, 1946, on his way home from Australia, was a notable son of a West of Scotland man. His boyhood, as the third son of a family of boys and girls, was spent at Crug near Montrose in Angus, where his father had become the parish minister. He was educated at Montrose Academy, and graduated M.B. Ch.B. with honours at Edinburgh University in 1903. During his student days he was a keen member of the old Volunteers, and in 1900 he enrolled in the Edinburgh and East of Scotland Hospital, serving with that unit in the South African War. On the termination of hostilities, he came back to Edinburgh and resumed his medical studies. In 1905 he obtained the D.P.H. of St. Andrews, and in the following year the Edinburgh M.D. After completing a term as house surgeon at Dundee and carrying out several appointments as locum tenens in industrial districts in England, he finally settled down in a country practice in the Cotswolds. Here, as a much loved and respected family doctor, he was able to develop his natural ability for combining work with play. Regularly he turned out with the hounds, becoming quite an authority on beagles as his handbook, *Beagles for Beginners*, will testify. For some eight years he practised successfully before moving to London with the intention of taking the F.R.C.S. and devoting himself to surgery. The war of 1914 intervened, and he found himself mobilized as an officer in the R.A.M.C.(T). He served with much distinction with the British Expeditionary Force on the Continent as lieutenant-colonel in command of the 1/2 Lowland Field Ambulance, being twice mentioned in dispatches and awarded the Military Cross. The French nation acknowledged his service to the cause by the award of the *Médaille d'Honneur avec étoile en vermeil*. On returning to civilian life, once more he found an outlet for his restless energy in the study of law, and in 1922 he qualified as barrister at law of Gray's Inn. About this time he joined the staff of the Ministry of Pensions, and it was here, as an established Civil Servant, that he spent the remaining years of his professional life till his retirement in 1942. In the 1939 war, advancing years compelled him to limit his role for leave service to the Home Guard, with which he served as medical officer. Johnson Scott's essentially tidy and unassuming manner were tempered by a pawky Scots wit. He was a timekeeper and quite at home in any corner. His kindly sympathy for the disabled ex-Serviceman was proverbial. A man of liberal outlook and a favourite with his colleagues, his untimely end is a loss to the

of health in the area. Marked improvements in housing conditions in the Durham rural districts can be largely attributed to his activities, which were essentially directed towards the relief of overcrowding and provision of new houses. In this particular area over 2,500 council houses had been erected when the recent war put an end to building operations. The sympathy of all who knew Dr Falconer and admired his achievements in Durham will go out to his widow. Their only son, Andrew, lost his life in 1941 when the ship in which he was serving in the Merchant Navy was torpedoed off the West Coast of Africa. Dr Falconer had been a member of the British Medical Association for over thirty years and he was also a Fellow of the Society of Medical Officers of Health. His chief interest was always in his work, but he was an active gardener, a keen angler, and was interested too in the cleaning of old pictures.

Dr MICHAEL WALTER WEST, of Earl's Court Road, London, was found drowned on Jan 1. Dr West, who was only 27, had been a student at St. Mary's Hospital and he qualified in 1942. He had been resident medical officer at the Shadwell Branch of the Queen Elizabeth Hospital for Children, and had served as a surgeon-lieutenant in the R.N.V.R. He was demobilized about a year ago and his tragic accidental death will be deeply regretted by all who knew him.

WILLIAM OSBORNE GREENWOOD died at Harrogate on Jan 8 at the age of 75. He was both a doctor and clergyman, being ordained to the curacy of the parish of Spofforth in 1930, but continuing his medical work at the same time. Dr Greenwood was a student of Leeds University. He took the L.S.A. in 1901, the M.B., B.S. of London in 1903, and the Leeds M.B. Ch.B. in 1905. He began his medical career at the Leeds General Infirmary, where he was house-surgeon to the late Lord Moynihan. From that time onwards he took an increasing interest in obstetrics and received the F.R.S.E.d. for his early work in connexion with scopolamine-morphine semi-narcosis during labour. Dr Greenwood, who in later years was an invalid, was well known for his lectures and treatises, many of which combined the subjects of religion and medicine. Two of his more important works were *Biology and Christian Belief*, which appeared in 1938, and his 1941 essay *Christianity and the Mechanists*.

Dr MICHAEL DEENY died at his home in Lurgan on Jan 10 at the age of 69. Dr Deeny was a native of Dungiven, Co. Derry, and was educated at St. Columba's College, Derry, and the Royal College of Surgeons, Dublin. He qualified in 1903 and was elected F.R.C.S.I. in 1933. After a brief period as house-surgeon in the Mater Hospitals of Belfast and Dublin, Dr Deeny went into general practice in Lurgan. He had been a member of Armagh County Council and in that connexion took a particular interest in the work of its Asylum Committee, of which he was still a member at the time of his death. He was also a J.P. and a large property owner. Dr Deeny was one of Lurgan's leading practitioners, and he had been a member of the British Medical Association since 1904. He is survived by two sons and a daughter, all of whom are members of the medical profession. The sympathy of all who knew and liked him in Lurgan will go out to his widow and to his children.

BRICE COLLYER of Croydon passed quietly away in his sleep on Jan 13. He was 77 and was working right up to the end. Brice Collyer went up to St. Bartholomew's Hospital in 1890 after a brilliant career at the Whitgift School, Croydon, where he was a contemporary of the late Sir James Berry. He qualified in 1893 and took the London M.D. in 1895. He filled in succession at Bart's the posts of house-physician, house-surgeon, and resident anaesthetist. He was invited to join the staff, but he preferred clinical work and went to Croydon, joining Drs. Duncan and Philpott as a junior partner. He became the senior partner in 1922 and continued his work in this Croydon practice until his death.

Sr Ernest Cowell writes: Brice Collyer's friends mourn his loss but will envy his end. It is as he wanted to die in harness. He belonged to a vintage period. Horder, Gow, and Landon Down were fellow students and remained lifelong friends. Collyer was a great clinician and he kept abreast of the times. He did a heavy round on Jan 12, rested in bed and died in his sleep in the early hours of the 13th. As a young man he acquired a reputation for sympathy which lasted throughout his long career. This began in Gloucestershire when he was doing a locum and was asked to visit a farmer to express his chief's condolences on the death of the farmer's wife. Collyer was a victim of hay fever, and when he reached the house after passing through several hayfields, his eyes were streaming. The farmer had never before seen such a sympathetic young man. Collyer used to tell this story with a chuckle.

Dr KENNETH FALCONER, for the past twenty years medical officer to the Durham Rural District Council, died at his home in Harrogate on Dec 27 at the age of 55. Dr Falconer was a graduate of Glasgow University. He took the M.B., B.S. in 1912, and for some years he was in private practice. He then joined the Durham Rural District Council and took the D.P.H. of Oxford in 1922, proceeded M.D. a year later. He was then appointed as an assistant school medical officer to the Oldham Education Committee. Then he was appointed as the Doncaster Urban Council, near which he remained until he occurred the post that he was to be medical officer for the appointment of M.O.H. to the Durham Rural District Council. He took over from the late Dr. [Name] in 1922 and became the first full-time medical officer

Although a staunch supporter of the British Medical Association, of which he had been a member for over fifty years, he never took an active part in affairs because of his deafness. He was a great lover of books, read wisely and well, and could always produce an apt quotation for any occasion. He will be greatly missed by many patients, to whom he was much more than a doctor. He was a true friend of many loyal admirers, down to the third or fourth generation. May he rest in peace. His name will be lovingly remembered by many of us for the rest of our lives.

Universities and Colleges

UNIVERSITY OF LONDON

The honorary degree of D.Sc. of the University was conferred on Sir Henry Dale, O.M., G.B.E., M.D., F.R.S., F.R.C.P., and Prof. E. D. Adrian, O.M., M.D., F.R.S., F.R.C.P., at the Foundation Day celebrations on Nov. 28, 1946.

Mr. John B. Hunter, M.Ch., F.R.C.S., has been re-elected Dean of the Faculty of Medicine in the University for the period 1946-8.

Geoffrey Bourne, M.D., F.R.C.P., has been appointed to the Readership in Histology tenable at the London Hospital Medical College from Jan. 1.

W. J. Martin, Ph.D., has been recognized as a Teacher of Medical Statistics at the London School of Hygiene and Tropical Medicine.

The title of Prof. Emeritus of Morbid Anatomy in the University has been conferred on Hubert Maitland Turnbull, D.M., F.R.S., F.R.C.P., who held the Chair of Morbid Anatomy at the London Hospital Medical College from February, 1919, until his retirement in September, 1946.

David Waldron Smuthers, M.D., has been appointed to the University Chair of Radiotherapy tenable at the Royal Cancer Hospital from Oct. 1, 1946.

The title of Reader in Anatomy in the University has been conferred on Richard Wheeler Haines, D.Sc., M.B., B.S., in respect of the post held by him at St. Thomas's Hospital Medical School.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Huntarian Oration entitled "Huntarian Ideals To-day" will be delivered by Sir James Walton, M.S., F.R.C.S., at the College (Lincoln's Inn Fields, W.C.) on Friday, Feb. 14, at 5 p.m. Fellows and Members of the College are invited to attend.

Medical Notes in Parliament

Applications for Special Diets

Sir Ernest Graham-Little, on Jan. 22, put a series of questions about special diets (annotations on this subject were "It Can Happen Here" (Dec. 28, 1946, p. 995) and "A Foretaste of Control?" (Jan. 11, p. 60)) letters on the same theme appeared in the *Journal* of Dec. 28, 1946 (p. 1001), Jan. 11 (p. 69), and (p. 157) Jan. 25.

Mr. Strachey told Sir Ernest that during the six months to Dec. 31, 1946, 235 applications which had been individually referred to the medical advisers of the Minister had been refused extra supplies of rationed foods as the result of the advice that was tendered. On the Special Diets Advisory Committee one member was under 40. Six members were in active practice as consultants. There were no general practitioners. The schedule of ailments was constantly under their review.

Sir Ernest then asked whether Mr. Strachey knew that the average age of these ten persons was 55 plus and that no member of the Committee had any acquaintance with general practice or personal experience of the doctor-patient relationship.

Mr. Strachey said he took the opportunity to inform the House of the system under which special allowances of rationed foods were given. In 1940 the Medical Research Council, at the instance of Mr. W. S. Morrison, set up a Food Rationing (Special Diets) Advisory Committee. The function of the Committee was to advise the Minister how best to dispose of the very limited amount of extra food available for invalids. This independent, honorary, and authoritative Committee advised the Minister of Food what categories of illness required special rations and established scales of the additional foodstuffs needed for each category. A list of these categories was circulated to every medical practitioner in the country. This admirable system was continued by successive Ministers of Food, and Mr. Strachey said he had every confidence in it. He paid

the warmest possible tribute to the eminent medical men who through all these years, carried out these arduous and difficult duties. He added that the Committee also considered applications from medical practitioners for additional foodstuffs for patients who would be excluded on a strict application of the scales of allowances laid down for each type of illness or condition. The Committee, therefore, acted as a court of appeal on borderline cases.

Sir Ernest inquired whether Mr. Strachey knew that the withdrawal from a patient, in the care of certain doctors in Birmingham, of an allowance of fat essential to the maintenance of the patient's life was followed by his death within a few days. He asked if Mr. Strachey would take steps to prevent a recurrence of this overriding of the opinion of doctors in actual charge of a patient.

Mr. Strachey answered that the certification from the practitioner that the patient suffered from the illness specified was always accepted without question. It was so accepted in this case, and the official concerned had to inform the practitioner that in such cases two pints of milk daily and three eggs a week were allowed, but not additional butter. The lay official transmitted an incorrect reason for refusing the butter. The practitioner then appealed, but, there being no reason given for regarding this case as in any way different from others in this category, the Committee confirmed the refusal, giving the correct medical reasons for doing so. In this sad case the patient died of inoperable cancer. Mr. Strachey's medical advisers informed him that the grant or refusal of an extra fat ration could have had no influence whatever upon the course of this disease. Extra milk and eggs were granted on medical grounds to this patient, and an allowance of butter was in fact granted, after being discontinued for only two days on compassionate grounds.

Mr. Churchill asked if there was any reason to believe that doctors had been abusing the right of giving advice as to extra diet to their patients in the past few years, and had this abuse amounted to such dimensions as to make an appreciable effect upon the general problem of food supplies.

Mr. Strachey said he would not like to accuse the medical profession of abuse in the matter, but the amount of extra milk given on medical priority grounds had caused concern to him and, on other occasions, to his predecessors, and to this medical Committee. The Ministry of Food had asked doctors, through the medical press, to have regard to the need, particularly in the case of milk, for restricting the extra amount granted on medical grounds.

Colonel Stoddart-Scott asked how frequently the Committee had met and why it took from Aug. 3 to Dec. 20 to get them to agree to provide white flour for a man who died on Dec. 23.

Mr. Strachey could not say whether the meeting was weekly or was arranged with regard to the business in view. The Committee had, voluntarily and in an honorary capacity, performed arduous and invidious functions as well as they could be performed. The average time taken to decide appeals was nine days.

Mr. Logan asked Mr. Strachey to give power to medical men to prescribe extra diets. Lives were saved by medical men and not by committees. Mr. Strachey said he could not possibly change the system. In the case of milk it certainly appeared that there must be some eminent and independent medical authority reviewing these cases.

Mr. Churchill suggested that if a doctor attended a patient and certified that the matter was urgent the diet should be given pending reconsideration by higher authority. Mr. Strachey said that would be good if it could be done. The medical Committee had laid down the categories of illnesses, ailments, and conditions which qualified for an extra ration. If a doctor certified that a patient was suffering from a condition which, on the scales laid down by the Committee, carried the extra ration, then the patient automatically and immediately received the ration.

Mr. Bower inquired whether Mr. Strachey knew that at least two persons had recently died after being refused additional quantities of rationed foodstuffs recommended by their medical advisers, and if he would now alter the present system in such a way as either to allow additional rations on the certificate of a registered medical practitioner or alternatively to ensure that the patient was seen personally by at least one member of the Special Diets Advisory Committee before additional ration were refused. Mr. Strachey could not accept the implication that deaths had resulted from the refusal of applications for additional rationed foods. He reaffirmed his confidence in the present system of dealing with these applications and said he proposed to continue it.

Sir Ernest Graham-Little asked Mr. Strachey to review the case of a patient discharged from hospital after a severe operation before convalescence, owing to shortage of beds, at

DIGOXIN 'B.W. & CO.'

Digoxin 'B W & Co', being a single pure glycoside of constant composition and activity, offers an unsurpassed degree of precision in digitalis therapy. Its rapidity of absorption and excretion, and the fact that it can be injected intravenously if necessary, are additional features of great importance.

The dosage of Digoxin 'B W & Co' is computed in milligrammes, not units.

Capsules

'ABIDON' WITH VITAMIN C

'Abidon' with Vitamin C Capsules are of particular service in affording protection against vitamin deficiency in growing children, pregnant and lactating women, convalescents and patients on restricted diet.

Each capsule contains —
Vitamin A 4500 International
Units Vitamin D 450 International
Units Vitamin B₁ (Aneurine Hydrochloride)
0.156 mgm Vitamin B₂
(Riboflavin) 0.05 mgm Vitamin C (Ascorbic Acid) 10 mgm

The normal dosage for children and adults is one capsule daily, in severe deficiency states 2 or 3 capsules daily.

Issued in vials of 25 and 100 capsules

Parke, Davis & Company

HAEMATOPOLYSIS

Hepolon is produced by special processes which conserve all the known haematopoietic principles of the whole liver. It approximates to the extract described by Gansslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anaemia but contains Whipple's factor, Wills's factor, riboflavin, nicotinic acid, and the haematonic minerals of liver, it gives no reactions for histamine or undesirable protein matter.

Ampoules of 2 c.c. box of 6 6/ box of 12 11/6 and box of 24 2/7
Rubber-capped vial of 10 c.c., 5/ and of 30 c.c. 12/6

HEPOLON

Contains in 100 c.c. the total soluble extractive matter of 250 g. fresh liver

ALLEN & HANBURY LTD, LONDON E 2

'BENZEDRINE' INHALER

Now in a modern plastic tube

The new plastic 'Benzedrine' Inhaler is a distinct improvement on the metal tube with which the medical profession has been familiar since 1932. Therapeutically as effective as ever it is at once more elegant in appearance and more convenient to use. This volatile vasoconstrictor is indicated in —

HEAD COLDS, SINUSITIS, NASAL CATARRH, HAY FEVER, and ASTHMA

Sample and literature on request

'BENZEDRINE' INHALER

Each tube is packed with
amphetamine 325 mg
oil of lavender 97 mg
menthol 32 mg

Vitamin Therapy — its uses and limitations

DIET AND DENTAL HEALTH

While the control of dental caries still lies in the future, certain nutrients will help to promote the health of teeth, gums and mucous membranes, more especially for the rising generation, but also for adults, for example

Calcium in a diet containing sufficient protein to promote absorption. Best given as milk or cheese.

Vitamin D whose distribution in foods is restricted.

Vitamin C to promote good denture formation and soundness of the gums.

Vitamin A for its effect on the enamel-forming organs.

For routine prophylaxis, the best all-round preparation is

COMPLEVITE

A single supplement for multiple deficiencies.

The recommended adult daily dose provides

vitamin A	4,000 i.u.	vitamin C	20 mg	iodine	} not less than 10 p.p.m. each
vitamin D	300 i.u.	calcium	160 mg	manganese	
vitamin B ₁	0.6 mg	iron	68 mg	copper

In MOMENTS of CRISIS . . .

the call is for

CORVOTONE

BRAND

NIKETHAMIDE B.P.

In addition to the 2 c.c. ampoules for injection CORVOTONE brand Nikethamide is available as a 25% solution for oral administration in bottles containing 1 fl. oz. and 100 c.c.

When rapid action is necessary in cases of accident poisoning, cardiac failure, etc., prompt and powerful stimulation is obtained by the use of Corvotone brand Nikethamide B.P. CORVOTONE possesses a pronounced stimulating effect on the vasomotor and respiratory centres as well as on the peripheral vascular system. It causes a sustained rise in blood pressure and stimulates respiration reflexly by its effect on the chemoreceptors of the carotid body.

As it has a wide margin of safety, the toxic dose being approximately ten times the therapeutic dose, Corvotone may be administered over long periods either orally or by injection.

FURTHER INFORMATION GLADLY SENT ON REQUEST TO

MEDICAL DEPARTMENT

BOOTS PURE DRUG COMPANY LTD
NOTTINGHAM ENGLAND

placed under the care of a general practitioner who applied for special dietetic allowances and was refused by his Department. Mr STRACHEY replied that in this case a doctor asked that a patient who was discharged from hospital after operations for general peritonitis, and already receiving extra milk and eggs, should also receive extra meat, cheese, sugar, butter, bacon, and bread. The application was refused as the Special Diets Advisory Committee recommended that the ordinary rations of foods other than milk and eggs were sufficient for convalescence from any illness. A review now would be inappropriate as the doctor had recommended the additional rations for six weeks from July 25, 1946.

Sir ERNEST GRAHAM-LITTLE further pressed Mr Strachey to review the decision on a case where a radiologist, to carry out a test for bile function on one of his patients, required to give a diet of eggs beaten up with milk, and was refused the grant of the eggs by the medical advisers of the Department who had no knowledge of the case. Mr STRACHEY said an application was made in June 1945, by a doctor for supplies of eggs for six unnamed patients to determine the function of the gall-bladder. The application was rejected because the Ministry's medical advisers considered that the same purpose would be served by other fats.

Mr STRACHEY furnished the following list of members of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council:

Sir Edward Mellanby (Chairman), Prof L S P Davidson, Sir Francis Fraser, Lord Horder, Dr R D Lawrence, Prof R A McCance, Dr M L Rosenheim, Dr Norman Smith, Prof J C Spence, Prof H P Himsforth, Lord Dawson of Penn, then President of the British Medical Association was an active member of the Committee until the time of his death.

German Doctors on Trial

Mr SOMERVILLE HASTINGS inquired on Jan 22 whether permission was given to Dr Kenneth Mellanby to travel to Germany in the uniform of a British war correspondent to talk to German doctors on trial at Nuremberg about their experiments on human beings, and what use would be made of his report.

Mr JOHN HYND replied that Dr Mellanby travelled as an accredited representative of the *British Medical Journal* and was given the usual facilities afforded to a Press correspondent. The use made of his report was a matter for the editor of the paper concerned. (See "Medical Experiments on Human Beings in Concentration Camps in Nazi Germany" in the *Journal* of Jan 25, at page 148.)

National Food Supplies

In the House of Lords on Jan 22 Lord DE L ISLE AND DUDLEY called attention to the food situation. He said food in greater quantity and variety was needed for the nation's energies.

Lord HENDERSON, replying for the Government said that during 1946 the world food situation deteriorated further, but in the British national diet the overall average intake of calories continued at only 5% less than it was before the war. Acute shortage in the world supply of major foodstuffs would continue throughout the crop year 1946-7. Some improvement was expected in oil and fat supplies. A reduction in the United Kingdom bread ration might be inescapable. In meat supplies it seemed likely that the Government would be no more than able to maintain in 1947 the same ration that had been issued last year. Egg and dried egg supplies would almost certainly be maintained at 1946 levels. Fish landings in the spring might become an embarrassment. There might be difficulty in maintaining the 2 oz ration of bacon. There was practically no hope of restoring the 3 oz ration during 1947. There was a prospect of 7 to 10% more sugar and of a small increase in the butter ration. He hoped no further cut would be necessary in the rations of soap or edible fats.

Lord CHERWELL said that at the end of the first year of peace the consumption of meat was down by 15%, of bacon by 33%, of cooking fat by 8%, of jam and marmalade by 16%, and of dried fruits by 15%. Lord Henderson's forecasts implied a further reduction of 100 calories or so a day in the British ration. The vast majority of the nation had a great deal more to eat before the war than they got now. Lord Addison as a medical man would not put forward the claim that the national health had never been better. Gastric ulcers and other gastric troubles were on the increase as were diseases of the nervous system and the cardiovascular system. The rising incidence of tuberculosis since the food had been reduced was unmistakable.

Lord ADDISON said restrictions had continued in the post war period because the needs of the world had been focused through the International Allocation Board. In Britain more milk was being produced this year than ever before in the winter months and a much larger quantity was consumed as

liquid milk. Adult consumption of milk had increased by 30%. Mothers and children had a priority allowance or seven pints a week, against a pre-war average of about half a pint. In three or four years a supply of groundnuts from Africa might relieve many anxieties with regard to fat supplies.

Lord CHERWELL expressed surprise that the Ministry of Food had made no statement on a disquieting paper published in the *British Medical Journal* by the Secretary of the Medical Research Council ('Diet and Canine Hysteria,' by Sir Edward Mellanby—Dec 14, 1946, p 885). Apparently 90% of the nation's flour was bleached by nitrogen trichloride. Examination of hysteria in dogs seemed to have proved conclusively that this was caused by bread bleached by the same process. Whether human beings were affected in the same way had not been proved but was not unlikely. In the first stage the dog got listless, apathetic, and averse to exercise. If this form of diet had the same effect on human beings it would not be conducive to increased production.

Notes in Brief

British Zone Rations—In the British zone of Germany for the period Jan 6 to Feb 2 of this year the weighted average of rations, including those of normal consumers, heavy workers, nursing mothers and other special classes is about 1,750 calories per day. This figure excludes the extra rations of children attending school in certain areas who receive a supplementary meal assessed at 300 calories daily up to 12 years and 490 calories daily over 12 years of age.

Medical News

Mr A. Dickson Wright will deliver the second of two Cantor Lectures before the Royal Society of Arts (John Adam Street, Adelphi, London, W.C.) on Monday, Feb 3, at 5 p.m. His subject is "Applications of Recent Physical Discoveries in Medical Diagnosis and Treatment." Mr Wright's first lecture, on the advances of modern surgery, was delivered on Jan 27.

A clinical meeting of the Scottish Group of the Association of Industrial Medical Officers will be held at the Pathology Museum, Glasgow Royal Infirmary, on Wednesday, Feb 5, at 3 p.m., when Dr J. Ferguson Smith will show a number of cases, some of which will have an industrial bearing, followed by a short talk on skin conditions. Time will be given for discussion and questions.

A meeting of the London Association of the Medical Women's Federation will be held at B.M.A. House on Wednesday, Feb 5, at 8.30 p.m., when Miss D. J. Collier, F.R.C.S., will speak on "The Influence of War Experience on Everyday Ear and Throat Treatment."

A meeting of the Society of Public Analysts and Other Analytical Chemists will be held at the Chemical Society's rooms (Burlington House, Piccadilly, W.) on Wednesday, Feb 5 at 6 p.m., when papers will be presented and discussed.

There will be a clinical meeting of the Medical Society of the L.C.C. Service on Thursday, Feb 6 at 3 p.m. at Sutton Hospital (Neurosis Centre), Brighton Road, Sutton, Surrey.

During February Sir William Fletcher Shaw will conduct examinations for the Royal College of Obstetricians and Gynaecologists in Sydney and Melbourne, Australia.

Postgraduates desiring courses at the Institute of Child Health, The Hospital for Sick Children, Great Ormond Street, London W.C.1, for three to six months or for shorter periods are asked to apply for reservations as early as possible before the date they wish to begin their studies, as vacancies are being filled well in advance.

The National Coal Board announces that Cuthbert Leslie Cope, D.M., F.R.C.P., First Assistant to the Nuffield Professor of Medicine, Oxford, has been appointed Director of Research (Human Problems) under the scientific member of the Board, Sir Charles Ellis.

An arrangement whereby the many thousand German scientific and technical documents held by Britain and the United States may be scrutinized in either country has been completed. Microfilm copies will be made available on an exchange basis to representatives of each nation. The responsible body in Britain is the Board of Trade, German Division (Documents Unit) and in America the Office of Technical Services, Department of Commerce.

Dr Carlos Chazariun, director of the Institute of Biophysics, University of Brazil and a specialist in metabolism, is on a visit arranged by the British Council, to this country to study medical developments. He is to meet British medical authorities in London, Oxford, and in Cambridge, where he will deliver a paper to the Society of Experimental Biology on "Some Aspects of the Discharge of the Electric Eel."

At a meeting of the directors of the Society for Relief of Widows Orphans of Medical Men, held on Jan 8, with Dr R A Young, president, in the chair, one new member was elected £1 815 was voted for the payment of the half-yearly grants to the widows in receipt of relief, those 65 years of age and over receiving £37 10s each and those under 65, £25 each. The question of the society's holding in railway debentures was discussed and will be raised again at the April meeting. Members who have been serving in H M Forces and who are now demobilized should notify the secretary of their present addresses, as unless the arrears of subscriptions are paid, membership is suspended. Membership is open to any registered medical man who at the time of his election is residing within a twenty mile radius of Charing Cross. Full particulars may be obtained from the secretary of the society, 11, Chandos Street, Cavendish Square, W 1.

The *British Journal of Nutrition* is another quarterly journal to make its appearance for the first time. It is not, perhaps, entirely new because it is replacing the *Proceedings of the Nutrition Society* and comes out under the same auspices. The Editorial Board under the Chairmanship of Dr S K Kon of the National Institute for Research in Dairying at Reading will consist of the following members: D P Cuthbertson, J N Davidson, R C Garry, G Graham, J Hammond, E M M Hume, I Leitch, W C Miller, B S Platt, J A B Smith, F Yates. The first number of the journal will appear during the first half of this year and we wish it every success.

Sir John Fraser, Principal of Edinburgh University has consented to become honorary president of the Scottish Association of Occupational Therapists. Lt Col Cunningham, of Edinburgh, has accepted the office of honorary vice president.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* infectious diseases were less prevalent than in the preceding week. There were decreases in the incidence of measles 600, scarlet fever 103, whooping-cough 102 and diphtheria 10. There was an increase in the notifications of dysentery 22.

Although the total number of cases of measles declined, an increased incidence was recorded in several counties, notably Staffordshire 143, Nottinghamshire 103, and Yorkshire North Riding 72. The largest falls were recorded in Warwickshire 155, Yorkshire West Riding 114 and Hertfordshire 85.

Slight decreases in the incidence of scarlet fever were general and no large local fluctuations were reported. The decrease in cases of whooping-cough was mainly contributed by the south-western counties, where 64 fewer cases were notified than in the preceding week. No changes of any size were recorded in the local returns of diphtheria.

Two fresh outbreaks of dysentery were recorded during the week. Hertfordshire, St Albans R D 24 and Yorkshire West Riding, Rotherham C B 14. The only other large returns for dysentery were Lancashire 13 and London 11.

In *Scotland* an increased incidence was recorded for whooping-cough 397, measles 239, acute primary pneumonia 70 and scarlet fever 20. Measles appears to be most prevalent in the cities of Aberdeen and Edinburgh.

In *Eire* a large increase in cases of whooping-cough 64 was mainly due to the outbreak in Dublin C B, where there were 101 cases. The notifications of scarlet fever and diphtheria decreased by 18 and 17 respectively.

In *Northern Ireland* a further 755 cases were notified in the epidemic of measles in Belfast C B.

Quarterly Returns for Northern Ireland

The birth rate during the September quarter was 22.9 per 1 000 and was the same as the average of the three quarters of the five years 1941-5. The infant mortality was 43 per 1 000 registered births and was 20 below the average of the five preceding September quarters. Maternal mortality was 2.5 per 1 000 births and was 0.7 below the five years' average. The general death rate was 9.8 per 1 000 and was 1.1 below the average rate for the five preceding three quarters. Deaths from infectious diseases were slightly less than half of the average of the three quarters during 1941-5. Deaths from pulmonary tuberculosis and from other forms were 179 and 55 and were 25 and 9, respectively, below the five years' average.

Week Ending January 18

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,226, whooping-cough 2,192, diphtheria 256, measles 11,087, acute pneumonia 1,223, cerebrospinal fever 58, dysentery 72, acute poliomyelitis 9, paratyphoid 6, typhoid 4. Deaths from influenza in the 126 great towns numbered 85.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan 11.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London), (b) The 16 principal towns in Scotland, (d) 10 principal towns in Northern Ireland. Space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	56	7	34	2	1	86	93	24	2	1

* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Includes primary form for England and Wales (London administrative county) and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire. It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct 26 Nov 2 9 16 23 30 Dec 7 14 21 28, 1946 Jan 4 and 11 1947.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Whooping-cough Immunization

Q—What public health authorities in this country are trying immunization against whooping-cough on a large scale? Can you refer me to the latest and most recent pronouncement on this subject?

A—This question probably refers to the controlled trials of pertussis vaccine being carried out by the Medical Research Council in conjunction with certain local authorities. These trials have so far been organized and are in progress in the boroughs of Tottenham and Wembley and in the City of Manchester. Two American vaccines are in use—the Sauer vaccine, made by Parke, Davis and Co., Detroit, and the Kendrick vaccine, made at the laboratories of the Michigan Public Health Department. Further organized trials will probably be carried out with new British vaccines, inquiries should be addressed to the Medical Research Council. An up-to-date review on immunization against whooping-cough is given by Dr J. Tudor Lewis in the *Medical Officer* July 6 1946, page 5.

Penicillin Treatment of Carbuncle

Q—What is the correct modern treatment of a carbuncle? Do daily intramuscular injections of 125,000 units of penicillin in beeswax and ethyl oleate alone produce a satisfactory blood level of the drug in this condition and is there evidence that this treatment reduces the incidence of metastatic complications? Is surgical incision contraindicated for the majority of cases? Should penicillin injections be combined with sulphathiazole by mouth?

A—The advent of penicillin therapy has to all intents and purposes done away with the need for surgical measures in the treatment of carbuncles. Penicillin, if given early enough and in sufficient quantity, will abort a carbuncle, if the condition has already reached the stage of subcutaneous necrosis, sloughs will separate automatically within three to seven days and can be picked out with dressing forceps. Should the resultant cavity be large enough to warrant it, immediate skin-grafting (after removal of sloughs) can be carried out with every confidence of success. In practically all cases the rapid relief of pain and toxæmia and of local oedema and tenderness can only be described as dramatic—taking place within a few hours. Dosage should approximate to 200,000 units a day for three to four days, and the penicillin can be given by intramuscular three-hourly injections of 20,000 units, by the 'intensive' method (200,000 units given into an intravenous drip over a two hourly period daily for two to three days), or by a single daily injection of 150,000 units in a "slow release vehicle". All these methods maintain a satisfactorily bactericidal blood level. Many instances have been reported of metastatic complications being both aborted and cured by penicillin administration. Generally speaking, penicillin alone will provide the required therapy, and sulphathiazole is better avoided as in a certain proportion of cases it will produce unwanted side-effects.

Postponement of Menstruation

Q—Is there any danger in using synthetic oestrogens by mouth to postpone the onset of a menstrual period (a) once in a while (b) repeatedly? What is the most satisfactory preparation and when and in what dosage should it be given? How long may one expect to hold off the bleeding and the associated symptoms? Supposing the patient had become pregnant in the previous four weeks would the foetus be endangered? In order to ensure that the chosen preparation did not cause unpleasant side-effects what would be the best time in the cycle to make a preliminary 'blank' trial?

A—If medication is to be limited to the premenstrual phase it is easier to postpone menstruation with progesterone than

with oestrogen. If stilboestrol is to be used, give 1 or 2 mg by mouth immediately after the end of a period and continue the dose thrice daily throughout the cycle. The object of this is to inhibit ovulation, and if this is achieved the next uterine bleeding (which will be anovular in type) will probably be postponed until seven to ten days after treatment is suspended. If, however, an ovum is liberated and fertilized it is possible that the heavy oestrogenic stimulus will inhibit progesterational changes in the endometrium and so prevent implantation. Once the ovum is successfully implanted, however, say after the twenty-second or twenty-third day of the cycle, stilboestrol is unlikely to disturb it. Oestrogens do not induce abortion in the human being although they do in some of the lower animals.

One or two test doses of stilboestrol could be given without harm at any time in the cycle, but perhaps the best time is during the ten days following a period. The deliberate postponement of menstruation by oestrogen and progesterone may be occasionally justified by some very special circumstance and probably does no harm. It should not, however, be done repeatedly for fear of upsetting the menstrual rhythm more permanently. Moreover the continued or frequent use of stilboestrol would cause endometrial hyperplasia and profuse uterine bleeding as well as some inhibition of pituitary and ovarian function.

Sulphonamides in Secondary Anaemia

Q—Is there any danger in giving sulphonamides in severe secondary anaemia for an accompanying disorder (for example gonococcal arthritis) providing granulocytes are in approximately normal proportions?

A—There is little danger in giving sulphonamides in such circumstances, certainly, if the accompanying infection indicates their use, they should not be withheld. Moreover leucopenia, and even agranulocytosis are not contraindications provided that there is associated sepsis which they are likely to control and that the initial reduction of leucocytes was not due to sensitivity to these drugs. It may be recalled that one rare manifestation of sensitivity to sulphonamides is an acute haemolytic anaemia, the gravity of which, in a patient already anaemic, is obvious. Secondly, there is some evidence that a mild depression of erythropoiesis follows prolonged medication with these drugs.

Stoking as a Cause of Industrial Disease

Q—During the war a stoker worked in a hospital where the stove hole was badly ventilated owing to the blackout. He now has extreme emphysema with chronic bronchitis probably due to the fumes. Is this an industrial disease and if so what steps should be taken to contact a certifying factory surgeon?

A—The occupation is not one specified in the Compensation Schemes, either under the Silicosis and Asbestosis Act of 1930 the Workmen's Compensation Act of 1943, or the Shipping Industry Compensation Scheme of 1946. Since apparently the stoker's work was carried on in a hospital the examining factory surgeon would in any case have no jurisdiction.

Distance Vision in Presbyopes

Q—In presbyopes vision for distance is commonly blurred on removing their glasses. This can hardly be due to accommodation for it occurs in quite elderly subjects. What are the cause and the treatment?

A—The assumption that the symptom mentioned cannot be due to accommodation is not quite valid. There is very little decline in capacity for accommodation after the age of 60, and a nonagenarian has a capacity for accommodation not much different from that of a man thirty years younger. It is reasonable to assume that the symptom is an expression of loss of resilience in accommodation. In the young the ciliary muscle acts briskly and the eye rapidly adjusts itself to any distance required. With the onset of presbyopia the muscle does not function so effectively, and the sclerosis of the lens makes this structure less plastic. In consequence there is effort involved to produce accommodation, and return to distance vision is also not so spontaneous. It is as if the eye, once adjusted for near vision, remains 'fixed' for some little time in that state before adjusting itself to distance. If this is so there is little

that can be done in the way of treatment. Nothing will make a senescent muscle younger and a rigid lens more plastic. It is, however, an accepted clinical fact that after debilitating illnesses these symptoms are common. The maintenance of good health and physical efficiency would therefore seem to be the only effective means of reducing these symptoms to a minimum.

Use of Powder in Massage

Q—*The use of powder in massage seems to be unphysiological and unhygienic. Would it not be better to use some oil which might also nourish the skin? What are the advantages and disadvantages of the use of powder as compared with oil or lanolin?*

A—The advantages of powder—provided it is of good quality—as a dry lubricant are the ease with which it is applied and with which it is stored or carried about, and its general cleanliness in use. It may have its disadvantages where delicate skins are concerned or where the skin is unusually scaly or dry through deficient sebum production, when oil is preferable. Oily lubricants are undoubtedly messy, and, except for those which are readily absorbed by the skin, they have to be removed by thorough washing with soap or by means of spirits if grease stains are to be avoided on garments or bed linen. The protection against water and physical agents afforded by an oil sodden corneal layer to the skin is too well appreciated to need stressing, but whether oil inunctions have any nutritive properties is problematic.

The use of powder as a lubricant for massage is no more unphysiological than the use of graphite in bearings is unscientific, and, provided always that the powder is clean, the 'unhygienic' qualities of the procedure will be determined solely by the state of cleanliness—or otherwise—of the patient's skin and the masseuse's hands.

Two stage Prostatectomy

Q—*In cases of enlarged prostate is it safe to proceed with the second operation if the blood urea is in the region of 60/70/80 or 90 mg per 100 ml? The patient is apparently in perfect health with good appetite, etc.*

A—The indications for proceeding with the second stage of the prostatectomy will depend on many other things besides the blood urea, for example, the urea concentration test, the total output of urine, and the general clinical condition. If the blood urea does not fall further with continued suprapubic drainage, and remains in the neighbourhood of 60/70, it may be justifiable to carry out an enucleation provided that other factors are favourable. Before doing so an intravenous pyelogram should be taken as this will show whether there is any gross lesion of the kidneys. Operation on a case in which the blood urea was consistently above 60 mg per 100 ml would inevitably carry with it some risk.

Increasing Stature

Q—*Can a man of 32 increase his height? I have seen it stated that a person's height can be permanently increased by a physiological thickening of cartilage.*

A—There is no method of increasing the true height of an individual once the epiphyses have united. It is impossible to produce the physiological increase in thickness of cartilage claimed. It is possible, of course, to increase the apparent height of one whose carriage is defective, by exercises designed to produce a more erect posture.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Holding of Several Appointments

G K holds one main appointment and several minor ones for which he is paid on a sessional basis. How should he be assessed?

** In strict law the income from each appointment is assessable under Schedule E, but we think that G K will be able to arrange with the local tax office for the main earnings to be assessed under Schedule E and the minor earnings aggregated into one sum and assessed under Schedule D—such an arrangement will obviously be convenient to both parties. G K is advised to raise the matter at once with the tax office so that the persons from whom he holds the minor appointments can be authorized to regard their payments as outside the P.A.Y.E. scheme.

Letters and Notes

Penicillin for Germany

Mr H CARTER and Dr YOLANDE FRIEOL write: Scientists particularly in the medical field have generally held to the principle that the latest discoveries for saving life or mitigating suffering should be used for the benefit of all mankind. It is therefore with grave concern that we note that owing to the completeness of the economic breakdown in Germany the patients in the German hospitals are largely deprived of some of those remedies with which their lives might be saved or their sufferings lessened. A few months ago we received a letter from Dr Ruth Smatznig of the children's hospital in Charlottenburg in the British Sector of Greater Berlin asking if we could send her even a small amount of penicillin for those cases requiring it most urgently. At that time there was, as far as she knew, apart from those hospitals receiving children under treatment for venereal disease, no children's hospital in Berlin in which penicillin was available for other infections amenable to penicillin. A little more penicillin has now been made available for other cases than venereal disease, but there is still far less than is required by all types of hospitals. We have recently sent out from the Ecumenical Refugee Commission of the World Council of Churches, in conjunction with Save Europe Now, 2,000 mega units of penicillin, which were flown across for us by the R.A.F. and which the Public Health authorities of B.A.O.R. are distributing for us among the hospitals in the British Zone and in Berlin. They would gladly receive a similar consignment from us monthly, if we can send it, and more is urgently required. Your readers are in a position to assess the seriousness of the situation and we would ask them to enable us to continue sending it. Donations can be sent to the Chairman of the Ecumenical Refugee Commission, 21 Bloomsbury Street, London W.C.1. This organization is duly registered under the War Charities Act.

Endogenous Depression in General Practice

Mr H. I. DEITCH, FRCS (Halifax) writes: Concerning the article by Dr C. A. H. Watts (Jan 4, p. 11) on the treatment of mild mental disorder and neurosis in general practice and the facilities at general hospitals, we have, attached to this hospital, a large department staffed by a psychiatrist and a physician for functional nervous disorders, which holds an out-patient session nearly every day of the week, has beds for in-patients to an unlimited extent and gives E.C.T. both to out-patient and to in-patients. The establishment of the department was easy and raised no administrative difficulties. Matron seconded members of her staff to the local mental hospital for training before treatment was commenced.

Dr P. E. F. FROSSARD (London, W.1) writes: In his article outlining "Endogenous Depression in General Practice" (Jan 4, p. 11) Dr C. A. H. Watts, while stressing the efficiency of electroconvulsion therapy and bemoaning the difficulty in persuading the mild depressive to go into a mental hospital for it, seems to be under the misapprehension that E.C.T. cannot be obtained in this country without recourse to in-patient treatment. He says: "In any case, in America (the italics are mine) E.C.T. is given to out-patients, and the majority of mild depressives could well be treated in that way" (p. 14). I would like to reassure Dr Watts that patients need not be sent as far as America for out-patient E.C.T. At the British Hospital for Functional Nervous Disorders—a clinic which has no in-patient department—E.C.T. is regularly administered to suitable cases referred by general practitioners and specialists. As in private practice, the patient is required to bring a friend to accompany him home after a short rest.

Extra Meat in Liver Disease

The Minister of Food announces that persons suffering from infective hepatitis (catarrhal jaundice), toxic jaundice and chronic hepatitis (cirrhosis of the liver) may now be allowed extra meat in addition to the household milk powder now permitted. The additional meat will be made available as follows: (1) *Infective Hepatitis and Toxic Jaundice*—Two extra rations of meat a week may be granted for a period of one month renewable on production of further medical certificates at monthly intervals. The grant will be made for a maximum period of four months. (2) *Chronic Hepatitis*—Two extra rations of meat a week may be granted for a period of three months, renewable on production of further medical certificates at three monthly intervals.

Record of Service

Mr J. ELLIOT SQUARE, FRCS (Plymouth) writes: I see in the Jan. 11 issue of your *Journal* (p. 78) that Dr C. H. Hall, of Watford, has been secretary of his medical society for 50 years. I can beat that as I am now in my 59th year as Hon. Treasurer of the Plymouth Medical Society, which was founded in 1794, and I believe the oldest provincial medical society in Britain except the Colchester Society.

LONDON SATURDAY FEBRUARY 8 1947

DUST CONTROL IN MEASLES WARDS

WITH A NOTE ON SULPHADIAZINE PROPHYLAXIS

BY

NORMAN D BEGG, MD

ELSPETH W SMELLIE, BM, BCh

AND

JOYCE WRIGHT, DM

(From the London County Council Eastern Hospital)

Allison and Brown (1936) showed that haemolytic streptococci may spread in measles wards as a secondary transmissible infection superimposed on the primary virus-caused disease. Their findings were confirmed by Wright, Cruickshank, and Gunn (1944), who showed in addition that dust particles are possibly an important means of streptococcal carriage in measles wards. They found that the oiling of blankets, bed linen, garments, and floors in a measles ward resulted in a 98% reduction in the numbers of haemolytic streptococci in the air during bed-making, when compared with the numbers in the air of an unoled control ward, and that the streptococcal cross-infection rate among the patients fell from 58.1% during a preliminary period with oiled floor alone to 18.6% when, in addition, oiled bed-clothes, garments, and ward linen were in use. The comparable cross-infection rates for the same periods in the unoled ward were 53.3% and 73.3% respectively. The method of laundry oiling was described by Harwood, Powney, and Edwards (1944).

Research on the control of air-borne infection was stimulated during the recent war by the occurrence of respiratory infection among men in barracks and other establishments. British workers demonstrated a great increase in numbers of dust-borne streptococci and other bacteria in the air of Army quarters and hospital wards during bed-making and sweeping, and successfully controlled dust-spread bacteria by the application of dust-laying oils to textiles and floors (van den Ende *et al*, 1940, 1941, van den Ende and Thomas, 1941, Thomas, 1941). American workers confirmed these observations and introduced new methods of oil application (Robertson *et al*, 1944, Commissions on Acute Respiratory Diseases and on Air-borne Infections, 1946, Loosli *et al*, 1946, Puck *et al*, 1946). In field trials they secured evidence that oiling floors and blankets reduced the incidence of haemolytic streptococcal infection among troops (Commission on Air-borne Infections, to be published).

Scope of the Investigation

Although the good results of dust control in a measles ward recorded by Wright, Cruickshank, and Gunn (1944) appeared clear-cut, it is notoriously difficult to make strict comparisons between one hospital ward and another. It seemed important, therefore, to repeat the experiment during another measles epidemic and in another hospital. At the same time nursing techniques and other matters, the importance of which had emerged during the first experiment, were standardized so far as possible. The investigation was undertaken during 19 consecutive

weeks in 1945 in two first-floor measles wards of identical size, design, and aspect. Each ward had a side-room for two cots. In the oiled ward (opened on Jan 28 and closed on June 7) the following dust-suppressive measures were taken. The floor of the main ward, which was of wood was treated with spindle oil immediately before the start of the investigation and monthly thereafter (the floor of the side-room, sanitary annexes, and passages could not be oiled, as they were of composition), all blankets, counter panes, sheets, pillow-slips, patients' garments, towels, and staff gowns were treated with technical white oil immediately before the start of the investigation and thereafter at each laundering. The blankets of each patient were disinfected after his discharge or transfer from the ward and were washed and re-oiled every four weeks. During the first three weeks the oiling was undertaken at the laundry of the British Launderers' Research Association, and during the rest of the investigation in the hospital laundry. The method used was that described by Harwood, Powney, and Edwards (1944). In the unoled ward (opened on Jan 25 and closed on May 31) no measures were taken against dust-borne infection. The floors of this ward and its side-room and annexes were of composition. In each ward the total bacterial and haemolytic streptococcal content of the air, and the cross-infection and complication rate due to haemolytic streptococci, were studied throughout the investigation. A third ward for the study of sulphadiazine prophylaxis was opened on Feb 14 and closed on May 19 1945. Particulars and results of this part of the investigation are the subject of a separate section of this report.

Ward Arrangements

1 The bed complement of each ward, which was normally 18, was raised to 20 (8 cots and 12 beds) during the investigation. The bed-spacing was 12 ft (366 cm) between bed centres. The length of each ward was 100 ft (30 m), the width 27 ft (823 cm), and the height 15 ft (457 cm). The ventilation turnover (between 4.30 and 6 a.m.), estimated once only, was five to seven changes in an hour. Each ward had a side-room with two cots reserved for patients with middle-ear suppuration.

2 Measles patients were allocated in rotation to the main wards, measles patients admitted with middle-ear suppuration were allocated in rotation to the side-rooms.

3 Toys and books were forbidden in the wards.

4 Mattresses, pillows, and blankets of each bed were disinfected (5 lb (2.27 kg) pressure for 30 minutes) at the start of the investigation, and thereafter on the discharge or transfer of each patient.

5 Barrier nursing was adopted for all patients with the following complications pneumonia, severe bronchitis, tonsillitis skin infection, and middle-ear suppuration

6 Patients with uncomplicated measles were discharged on their tenth day in hospital

7 Swabs for nasal toilets were sterilized in dressing drums, nurses were instructed to use a "no-touch" technique and to wash their hands in a solution of "O-syl" between each nasal toilet

8 Convalescent patients were restricted to their own bed area

Routine Procedures

Air Sampling—The bacterial content of the air was investigated by means of a slit sampler (Bourdillon, Lidwell, and Thomas, 1941) Air samples were taken once weekly in each ward during bed-making (5 to 6.30 a.m.) and during sweeping (8.30 to 9.30 a.m.) The slit sampler, on a trolley, was moved from one bed to the next as each in turn was made During sweeping the machine remained at a fixed central point in the ward The height of the slit, through which air was drawn at the rate of 1 cu ft (28.317 c.m.) per minute, was 34.5 in (87.6 cm) from the floor For measuring the total bacterial content of the air, blood agar plates were exposed in the slit sampler for one to three minutes and were incubated aerobically for 24 hours at 37° C The number of bacterial colonies on each plate was counted, though on crowded plates only an approximate count could be made For measuring the haemolytic streptococcal content of the air, gentian-violet blood agar plates were exposed in the slit sampler for 5 to 15 minutes The number of colonies of haemolytic streptococci on each plate was counted after 24 hours' incubation aerobically at 37° C

Cross-infection Criteria—Swabs were taken from the nose and throat (and from the ear discharge, if any) of every patient immediately before admission to the wards, then once weekly and on the day of discharge or transfer Nose and throat swabs were taken once weekly from the ward and laboratory staffs and from the medical officers Swabs were plated on gentian-violet blood agar plates and incubated aerobically for 18 hours at 37° C Cross-infection was judged to have occurred if a patient, between his third hospital day and the day of his discharge or transfer from the ward, was found to have in his upper respiratory tract haemolytic streptococci of Groups A, C, or G which were not present on the day of, or the day after, admission It was intended to take swabs in the receiving-room from the skin lesions of all new patients, but this was not always practicable as some patients had multiple or crusted lesions

Complication Rate—A daily round of all patients in the three wards was made and any complication or rise of temperature noted Appropriate swabs were taken, plated on gentian-violet blood agar, and investigated for the presence of haemolytic streptococci after 18 hours' incubation aerobically at 37° C

Serological Investigation of Haemolytic Streptococci—Representative colonial forms of haemolytic streptococci were picked from gentian-violet blood agar plates to blood broths, which, after 18 hours incubation aerobically at 37° C, were stored in the refrigerator for subsequent serological examination All haemolytic streptococci thus stored were tested for Lancefield group by the formamide method (Fuller, 1938) Group A streptococci were tested for serological type by the Griffith agglutination method Strains which had been derived from patients and which failed to type by agglutination were tested by the precipitin typing method (Swift, Wilson, and Lancefield, 1943) so also were representative strains from a large number of Group A

streptococci which gave agglutination reactions with type 13 and B3264 sera Strains which failed to give satisfactory reactions were recorded as "type not found"

Results of Investigation

Air Sampling

Air samples were taken once weekly during bed making and sweeping in each main ward and also in the side-room, if occupied The results in the unoled and the oiled wards are shown in Table I

TABLE I—Counts of Total Bacteria and of Haemolytic Streptococci in the Air of the Unoled and of the Oiled Ward during Bed making

1 cu ft = 28.317 c.m.

The table shows that the reduction in the mean total bacterial count of the air of the oiled ward during bed making was 92.3% when compared with the figure for the unoled ward This reduction indicates that the oiling of the bed-clothes, etc., was effective in controlling bacteria carrying dust particles A striking feature of the investigation was the comparatively low counts of haemolytic streptococci in the unoled ward Only on three occasions did the counts in the unoled ward rise above a figure of 50 haemolytic streptococci per 100 cu ft (2.832 m³) of air, and in eleven of the seventeen morning samplings the counts were below 10 per 100 cu ft The two highest counts—180 and 142 haemolytic streptococci respectively—were largely accounted for by two plates on one of these 91 streptococcal colonies were collected from 10 cu ft (0.28 m³) of air, and on the other 82 from 12 cu ft (0.34 m³) Both samplings had been taken from the surroundings of patients with numerous streptococci in the nose and throat The reduction in the mean haemolytic streptococcal count during bed-making in the oiled ward was 94.7% when compared with the figure for the unoled ward

Table II shows the counts of total bacteria and haemolytic streptococci in the air of the unoled and of the oiled ward during sweeping

The table shows that the reduction in the mean total bacterial count of the air of the oiled ward during sweeping was 79.1%, when compared with the figure for the unoled ward The counts of aerial haemolytic streptococci obtained during sweeping showed the same irregularity as those obtained during bed-making On the whole the sweeping counts were low, from ten of the seventeen morning samplings no haemolytic streptococci were isolated One high count—150 per 100 cu ft of air—was obtained this occurred on the morning on which a high count was obtained during bed-making and may have been explained

by the disturbance for nursing purposes of the bed of a heavy carrier during the sweeping. The reduction in the mean haemolytic streptococcal count during sweeping in the oiled ward, when compared with the figure for the unoled ward, was 95.9%.

Table III shows the counts of total bacteria and haemolytic streptococci in the air of the side-rooms of the unoled and oiled wards during bed-making and sweeping. In this connexion it should be recalled that the floors of both side-rooms were of composition and that therefore the side-room attached to the main oiled ward could not be treated with spindle oil. Air samples were taken from the side-rooms only when they were occupied, this accounts for the absence of readings in some weeks.

The reduction in the mean total bacterial count in the air of the side-room of the oiled ward was during bed-making 95.5% and during sweeping 72.9%. Corresponding reductions in the mean haemolytic streptococcal counts were 59.2% and 85.5%. Patients with heavy streptococcal infections of the upper respiratory tract were being nursed in the side-room of the oiled ward on the three occasions when haemolytic streptococci were recovered from the air during bed-making. It is possible that some of these streptococci resulted from droplets, as the children were apt to cough in the early morning alternatively, some may have arisen from the dressings applied to their ears.

Eighty-one colonies of haemolytic streptococci isolated from the air of the unoled ward were tested serologically. Of these, 79 belonged to Group A, one to Group C, and one to Group G. Of the Group A strains, 1 was type 1, 3, type 11, 3, type 11/28, 1, type 12, 8, type 25, 3, type "impetigo 19", and 60, "type not found". Twenty-seven colonies of haemolytic streptococci from the oiled ward were tested, of these, 23 belonged to Group A and 4 to Group G. Of the Group A strains, 1 was type 4/24, 1, type 6, 14, type 12, 1, type 25, and 6, "type not found".

Cross infection Incidence

During the course of the investigation 186 measles patients were nursed in the unoled ward. Of these, 23 became cross-infected in the upper respiratory tract with Group A, C, or G streptococci, giving a cross-infection incidence of 12.4%. Serological examination of the cross-infecting strains yielded the following results: 15, Group A (1, type 2, 1, type 4/24/29, 4, type 12, 2, type 25, 1, type 27, 1, type 29, and 5, "type not found"); 3, Group C and 5, Group G. In 20 of the cross-infected patients the streptococcus was first isolated from the throat, in 1 from the nose and throat, in 1 from the nose, and in 1 from the ear. Ten of the cross-infections were first discovered in the swabs taken on the day of the patient's discharge from hospital.

In the oiled ward 190 measles patients were nursed. Of these, 39 became cross-infected in the upper respiratory tract with Group A, C or G streptococci, giving an incidence of 20.5%. Serological examination of the cross-infecting streptococci yielded the following results: 33, Group A (1, type 2, 4, type 4/24/29, 1, type 6, 1, type 11, 1, type 11/27/28, 12, type 12, 1, type 14/R491, 1, type 22, 3, type 25, 1, type 29, 2, type "impetigo 19", 5, "type not found"), 4, Group C and 4, Group G. Double cross-infections with different serological types occurred in two patients. In 26 of the patients the cross-infecting streptococcus was first isolated from the throat, in 7 from the nose and throat, in 5 from the nose, and in 1 from the ear. Eleven of the cross-infections were first discovered in the swabs taken on the day of the patient's discharge from hospital. One small outbreak of type 12 streptococcal infection occurred in the oiled ward. The first cross-infection was discovered on Feb 6. Possible sources of infection were a child admitted to the adjacent cot with type 12 streptococci in his upper respiratory tract, and a nurse who developed type 12 streptococcal tonsillitis on the day on which the ward was opened. By the following week three other children had become cross-infected with type 12 streptococci, and by the following week three more children and one nurse.

Complication Rate

None of the 186 patients in the unoled ward developed middle-ear suppuration definitely attributable to streptococcal cross-infection. One child, admitted with non-streptococcal otorrhoea, acquired a Group G streptococcus in the ear discharge. Another child, admitted with Group

A streptococci in the nose and throat, developed left otorrhoea due to Group A streptococci since all the streptococci isolated from this patient failed to type, it was not possible to decide whether the otorrhoea was or was not due to cross-infection. Two patients in the unoled ward developed "late" middle-ear suppuration due to pneumococci.

Of the 190 patients admitted to the oiled ward, only one case of "late" middle-ear suppuration (that is, occurring on or after the sixth hospital day) could be attributed to streptococcal cross-infection (Group A, type 12). One other child in this ward developed "late" otorrhoea, also due to type 12 streptococci, but she was a throat carrier of this type on admission.

Other complications among patients after admission were also few. Those which might possibly have been due to cross-infection were as follows. In the unoled ward: mild conjunctivitis, Group A, "type not found", follicular tonsillitis, Group G, type 25. In the oiled ward: fissure in angle of mouth, Group A, "type not found", tonsillar plugs, Group C, fissure of lip, Group A, type 12, fissure of lips and cervical adenitis, Group A, type 12.

Sources and Spread of Infection among Patients

1 Unoled Ward

(a) *Carrier Rate on Admission*—Over the whole period of the investigation the carrier rate of haemolytic streptococci in the nose and/or throat of patients on admission was 19.7%. Of the 37 streptococcal strains, 26 were Group A (1, type 1, 2, type 2, 6, type 4/24/29, 1, type 8, 1, type 11, 3, type 12, 2, type 25, 1, type 27, and 9, "type not found"), 7, Group C, and 4, Group G.

(b) *Heavy Nasal Carriers*—Hamburger, Green and Hamburger (1945) stated that patients with heavy streptococcal infection of the nose are more liable than others to contaminate their surroundings and should therefore be regarded as "dangerous" carriers. In this investigation it was found that, among the 186 patients nursed in the unoled ward, only 9 were heavy nasal carriers of haemolytic streptococci, this may possibly account for the comparatively small numbers of haemolytic streptococci found in the air.

(c) *Middle-ear Suppuration*—Seven patients with middle-ear suppuration were admitted direct to the side-room of the unoled ward. Only one of these infections was due to streptococci (Group C). One patient was removed from the main ward to the side-room on the development of otorrhoea due to streptococci (Group A, "type not found"), and two on the development of pneumococcal otorrhoea.

2 Oiled Ward

(a) *Carrier Rate on Admission*—The carrier rate of haemolytic streptococci in the nose and/or throat of patients on admission was 20.5%. Of the 40 streptococcal strains, 30 were Group A (1, type 2, 1, type 4/24/29, 1, type 6, 3, type 11, 6, type 12, 1, type 14, 1, type 24, 2, type 25, 1, type 27, 1, type 29, 2, type "impetigo 19", 10, "type not found"), 9, Group C, and 1, Group G.

(b) *Heavy Nasal Carriers*—Of the 190 patients who were nursed in the ward, only 11 were heavy nasal carriers of haemolytic streptococci.

(c) *Middle-ear Suppuration*—Eleven patients with middle-ear suppuration were admitted direct to the side-room of the oiled ward. Five of these children were infected with haemolytic streptococci (Group A, 1, type 6, 1, type 24, 1, type 29, 1, "type not found" and 1, Group C). One of these patients was found not to be suffering from measles and was removed from the ward after 24 hours. Two patients who developed streptococcal

otorrhoea (Group A, type 12) were removed to the side room from the main ward.

Sources and Spread of Infection among Staff

1 *Unoled Ward*—Haemolytic streptococci were isolated from the upper respiratory tract of 6 of the 32 nurses or domestic helpers (18.8%) who worked in the ward during the course of the investigation. The distribution of the streptococci was as follows: Group A, 1, type 4/24/29, 1, type 11, 1, type 25, 3, "type not found". In addition one nurse suffered from a septic finger due to Group A, type 25, streptococci and was taken off duty.

2 *Oiled Ward*—Haemolytic streptococci were isolated from the upper respiratory tract of 8 of the 31 nurses or domestic helpers (25.8%) during the course of the investigation. The distribution of the streptococci was as follows: Group A, 2, type 2, 2, type 12, 1, type 12 and "impetigo 19", 1, type 27, and 2, "type not found". One of these nurses developed a type 12 streptococcal tonsillitis and was taken off duty.

3 *Medical and Laboratory Staff*—Of the ten members of the medical and laboratory staff who visited the wards two were intermittent carriers of streptococci (1 Group A "type not found" and 1 Group A, type 25), and 1 had streptococci (Group A, type 1) in the throat on two occasions.

Skin Conditions

If we include in the category of skin sepsis not only obvious sepsis such as impetigo, boils, etc., but also skin lesions which are commonly secondarily infected, such as burns, infantile eczema, seborrhoeic dermatitis, and so on, we find that the distribution of cases was not equal between the two wards. In the oiled ward 26 children had skin sepsis on admission and 15 developed lesions subsequent to admission. In the unoled ward the corresponding figures were 14 and 16. This may have some importance in the subsequent interpretation of results, since the bacteriological cross-infection rate for all children with skin sepsis on admission was 27.5%, which is higher than the mean of 16.5% for all cases in both wards. Individual examples presented themselves during the study which showed that respiratory infection was probably due to auto-inoculation from a skin lesion. (Example J B, aged 2 years, when admitted on April 6, 1945, the nose and throat swabs contained no haemolytic streptococci, but an impetiginous lesion had numerous type 25 streptococci. On April 12 the nose and throat swabs had a fair number of type 25 streptococci.)

The view has been expressed that the oiling of bed clothes is not free from drawbacks, as some of the oils are dermatitic (Mitman, 1945). Our experience was that among 190 patients nursed in oiled bed-clothes and garments, only 5 (2.6%) showed any evidence of skin irritation. This was mild and ceased immediately on discontinuing to wear an oiled vest. Attempts to incriminate the dermatitic element in the emulsion failed because, apart from these few cases early in the experiment, skin irritation neither appeared naturally nor could be produced artificially by the prolonged wearing of garments impregnated with various types of emulsion. It must be remembered that during the war high degrees of purity, particularly of the emulsifying agents, could not always be attained by the manufacturers. Given reasonable standards in this respect, our experience of this particular oiling method indicates that the risk of skin irritation is negligible. If any anxiety is felt on this account it may be dismissed by omitting the oiling of the inner garments such as vests which by themselves cannot contribute much to the risk of dust-borne infection.

Clinical Severity

The investigation started in late January, during a spell of old weather which was followed by a mild late winter and spring. Some of the patients admitted early in the period were acutely ill and presented the usual diagnostic difficulty between severe uncomplicated measles and early bronchopneumonia. This phase lasted for only two to three weeks. Six patients in the oiled ward and five in the unoiled ward suffered from bronchopneumonia. In the oiled ward 65 of the 190 patients received sulphonamide therapy, and in the unoiled ward 58 of the 186 patients, with few exceptions the drug used was sulphadiazine. Taken over the whole period of the investigation the patients were only mildly ill, and, latterly, very few seriously ill patients were seen. It should be noted, too, that throughout the investigation there were close restrictions on measles admissions in London, the aim being to admit to hospital only on account of severity of attack or of poor home conditions.

During the period of the investigation 151 measles patients were nursed in wards other than those used for the dust-control work. Of these, 130 were allocated to a chemoprophylaxis study ward which is the subject of a separate report, the remaining 21 were housed elsewhere in the hospital for the following reasons: 14 were male patients over the age of 7 years, 3 were convalescent on admission, 3 had both pertussis and measles, and in 1 the diagnosis was in doubt. None of these patients had middle-ear suppuration either on or after admission, two had bronchopneumonia.

Discussion

Detailed bacteriological investigation was made in two measles wards at the North-Western Hospital during the 1943 epidemic. In both wards secondary type 6 streptococcal outbreaks occurred and resulted in high cross-infection and middle-ear suppuration rates. In the air of the unoiled ward an average count of 253 haemolytic streptococci per 100 cu ft (2 832 m³) was obtained during bed-making. In the oiled ward aërial streptococci during bed-making were 98% less and during sweeping 99% less than in the unoiled ward. The use of dust-control measures was coincident with a fall in the rate of type 6 streptococcal cross-infection from 58.1% to 18.6% and of middle-ear suppuration (due to this cross-infection) from 18.4 to 2.8% (Wright, Cruickshank, and Gunn, 1944, Wright, 1945). At the Eastern Hospital in 1943 a high incidence of "late" middle-ear suppuration—21%—was also found. Bacteriological investigations were not made, but it may be reasonably supposed that the high otorrhoea rate was due to secondary streptococcal infection and that the ward epidemiology was in fact similar to that of the North-Western Hospital.

The most striking feature of the 1945 investigation at the Eastern Hospital lay in the unoiled ward, which had a comparatively low cross-infection rate (12.4%), no cases of middle-ear suppuration due to streptococcal cross-infection, and a low streptococcal content of the ward air. Aërial streptococci in this ward, even including two plates with high counts, yielded an average content during bed-making of only 29 haemolytic streptococci per 100 cu ft of air, on four occasions no haemolytic streptococci were isolated from the ward air during the bed-making period and on even other occasions counts of less than 10 per 100 cu ft were obtained. The unoiled ward therefore failed to fulfil its function of supplying a yardstick against which possible benefits of dust control in the oiled ward could be measured.

Several other differences were noted between the results of the investigation in 1943 at the North-Western Hospital and in 1945 at the Eastern Hospital. With few exceptions

the cross-infections in 1943 were due to type 6 streptococci. Mass invasion with this type occurred, as shown both in the number of patients infected and in the abundance of the streptococci yielded from the swabs. In 1945, 11 serological types of Group A and also Groups C and G streptococci were responsible for the cross-infections. Heavy streptococcal growth was obtained in 1943 from 72% of the cross-infected patients, whereas in 1945 only 25% of the cross-infections were heavy invasions and 42% were scanty. The degree of nasal cross-infection also differed. In 1943, 60% of the cross-infections resulted in a heavy streptococcal infection of the nose, while in 1945 only 8% were of the heavy nasal type.

The streptococcal cross-infection rates among patients in the unoiled and the oiled ward in 1945 were 12.4% and 20.5% respectively. Both wards had therefore a comparatively low cross-infection rate of the same order as the 18.6% rate which was regarded as satisfactory for the oiled ward in the 1943 investigation. The low degree of aërial contamination by streptococci in both wards suggests that the cross-infections were caused by a type of spread which was not air-borne. Possibly they were due to contact infection, for which there is ample opportunity in the catarrhal stage of measles. The fact that cross-infections of this type were more numerous in the oiled than in the unoiled ward could not be explained. Undetected differences in nursing technique in the two wards were a possible cause, since in field trials of this type an unavoidable variable between the experimental and the control ward lies in their different nursing staffs. In spite of careful alternate allocation of patients to the wards, two factors acting unfavourably to the oiled ward were observed: (a) it had a higher admission rate of type 12 streptococci—the only streptococcal type which showed signs of "communicability" and "virulence", and (b) it had a higher admission rate of skin sepsis and streptococcal otorrhoea cases.

Complications due to streptococcal cross-infection were exceedingly few in 1945. Only one patient out of a total of 376 nursed in the two wards developed "late" middle-ear suppuration definitely attributable to streptococcal cross-infection—an incidence of 0.27%. The safety of the measles wards of 1945 contrasted strongly with the risks in 1943, when one in every five patients contracted middle-ear suppuration. It is evident that conditions favourable to the spread of streptococci in measles wards vary considerably from one epidemic year to another. The results of the 1945 investigation need in no way discourage further trials of dust suppression by oiling. It is possible that the unfavourable conditions of 1943 may recur in subsequent measles epidemics. In such an event the introduction of dust control may again assume importance as a measure in preventing cross-infection.

Summary

An investigation into the control of dust-borne haemolytic streptococci was carried out in two identical measles wards at the Eastern Hospital for a period of 19 weeks in the spring of 1945. In one, the oiled ward all bed-clothes, patients' garments, and ward linen were treated in the hospital laundry with technical white oil and the floor of the main ward was oiled. In the unoiled ward no anti-dust measures were taken. In both wards the air was sampled for total bacteria and for haemolytic streptococci during bed-making and sweeping, and the streptococcal cross-infection and complication rates were recorded.

The oiling methods were successful in suppressing dust-borne bacteria. This was shown by the fact that the mean total bacterial count was reduced when compared with the count for the unoiled ward by 92.3% during bed-making and by 79.1% during sweeping. Counts of aërial haemolytic strepto-

cocci in the unoled ward varied considerably from week to week and in general were of a low order. On three occasions comparatively high counts were obtained 180, 142 and 80 streptococci per 100 cu ft (2 832 m³). On four occasions, however, no haemolytic streptococci were collected during a complete bed-making round and on seven other occasions the count was below 10 per 100 cu ft. The same irregularity of aerial contamination by haemolytic streptococci was found during sweeping.

The cross-infection rate among 186 measles patients nursed in the unoled ward was 12.4%, and among 190 patients in the oiled ward, 20.5%. These cross-infections the rates of which were comparatively low for such a highly susceptible group as measles patients appeared to be due to contact rather than to air-borne infection. The fact that this type of cross infection was higher in the oiled than in the unoled ward was unexplained. The complication rate due to streptococcal cross-infection was exceedingly low, only one case of streptococcal otorrhoea due to cross-infection occurred among the total of 376 patients nursed in the two wards, making an incidence of 0.27%.

Striking differences were found from the results recorded in an earlier and similar investigation at the North Western Hospital in 1943. In the unoled ward there a high haemolytic streptococcal count was found in the ward air and secondary type 6 streptococcal spread caused a cross infection rate of 72% and a 'late' middle ear suppuration rate of 18.5%. In the unoled ward of the 1945 investigation at the Eastern Hospital the streptococcal content of the air was in general low the cross-infection rate was 12.4% and no case of 'late' middle ear suppuration due to streptococcal cross-infection occurred. The unoled ward in 1945 therefore failed in its function of acting as an adequate control ward against which possible benefits of dust control by oiling could be measured.

It is evident that conditions favourable to secondary streptococcal epidemics in measles wards vary considerably from year to year. The results of the investigation at the Eastern Hospital in 1945 should in no way discourage further trials of dust control by oiling. Should the unfavourable conditions of 1943 recur in consequent measles epidemics dust-suppressive measures may again assume importance in the control of cross infection.

SULPHADIAZINE PROPHYLAXIS IN MEASLES

Large-scale studies of sulphadiazine prophylaxis of respiratory infections in the United States Navy during the war years (Cohurn 1944) encouraged an attempt to evaluate chemoprophylaxis of streptococcal cross-infection in measles. For this purpose a third study ward was set up as has been mentioned in the main report on the dust control investigation. The hope of thereby comparing cross-infection rates among patients having sulphadiazine prophylaxis with those in the control ward was prevented by differences, some unforeseen and some unavoidable between the two wards. The sulphadiazine patients had to be nursed in a ground floor ward with blast-protected windows whereas the control ward was on the first floor and had unprotected windows. The sulphadiazine ward could not be opened until three weeks after the control ward and was closed two weeks earlier. Also owing to an oversight due to changes of staff, discharge swabs from 17 of the 130 sulphadiazine patients were omitted. A further difficulty in comparison arose because nearly one third of the patients in the control ward received sulphonamides therapeutically. For these reasons the results must be regarded as quite inconclusive, but they are briefly described here since they include evidence on sulphonamide levels attainable with small doses of the drug.

The ward regimen was as follows. Sulphadiazine was given to all patients the daily dose being 0.25 g. for 0-2 years of age, 0.25 g., 3-9 years, 0.50 g., 10-16 years, 0.75 g. over 17 years, 1 g. The first dose was given soon after admission and subsequent doses between 9 and 10 a.m. daily up to and including the day of discharge. From 18 patients blood samples were taken 24 hours after the daily dose and were estimated for sulphadiazine content. The three samples from the 0-2 years group contained 2.19 and 1 mg. per 100 ml. of blood, the eleven

from the 3-9 years group contained a mean of 1.95 with a range from 0.43 to 0.6 mg. per ml. of blood, the two from the 10-16 years group, 3 and 1.2 mg., and the two from the over 17 years group 2.5 and 2.7 mg.

The following results were recorded for the ward.

Air Sampling.—During bed-making the mean total bacterial count was 3,880 and during sweeping 1,570 per 100 cu ft (0.28 m³) of air (2,360 and 1,230 respectively per 100 cu ft in the control ward). During bed making the mean haemolytic streptococcal count was 3.7 and during sweeping 1.6 per 100 cu ft (2.832 m³) of air (28.9 and 14.2 respectively per 100 cu ft in the control ward).

Cross-infection Rate.—Of the 130 patients admitted to the ward 13 (10%) became cross infected with Group A streptococci (1 type 1, 2 type 4/24/29, 1 type 11/28, 1, type 12, 1, type 22, 1, type 25 and 6, 'type not found'). None was cross-infected with Group C or G streptococci.

Complication Rate.—None of the patients developed otorrhoea or other complications attributable to streptococcal cross-infection.

Sources and Spread of Streptococcal Infection

Among Patients.—(a) *Carrier Rate on Admission.* The carrier rate of haemolytic streptococci (Groups A, C or G) among patients on admission was 10.8%. Of the 14 strains isolated 12 were Group A (3 type 4/24/29, one type 11, 1, type 12, 3 type 22, 2 type 25, 2, 'type not found'), 1, Group C, and 1 Group G.

(b) *Heavy Nasal Carriers.* Only three of the 130 patients were heavy nasal carriers of haemolytic streptococci.

(c) *Middle-ear Suppuration.* Five patients were admitted to the side room with middle-ear suppuration, one only of which was due to streptococci (Group A type 11).

Among Staff.—Haemolytic streptococci (Group A types 11 and 12) were isolated from only two of the 27 nurses and domestic helpers who worked in the ward during the investigation. The type 12 streptococcus was isolated from a domestic worker with tonsillitis.

Skin Infections

Eleven children in this ward had skin sepsis on admission in contrast to 14 in the control ward. It is interesting to note however, that in the three study wards—the sulphadiazine ward, the oiled ward and the control ward—the numbers of children admitted with frank impetiginous lesions were 8, 9, and 6 respectively and that these gave rise to 4 secondary cases of impetigo in the sulphadiazine ward, 1 in the oiled ward, and 1 in the control ward. The four secondary cases in the sulphadiazine ward were of the bullous type and occurred as an explosive little outbreak which suggested that sulphadiazine in these doses has very doubtful prophylactic value against the spread of this form of skin sepsis.

Toxic Effects

No toxic effects were noted. In this connexion it must be emphasized that owing to the general mildness of the measles attacks in the whole period of the study and the particular absence of complications in the ward the period of inpatient treatment and hence the sulphadiazine administration was short. Most patients were discharged on their tenth day in hospital and the longest stay of any patient was 31 days.

Summary

The complete absence of complications attributable to streptococcal cross infection in the sulphadiazine ward and the low bacteriological cross infection rate justify a further attempt to evaluate the difficult question of sulphonamide prophylaxis in measles. No other significance should be attached to the results of this study.

The daily ingestion of 1 g. of sulphadiazine with downward adjustments for age to 0.25 g. attained minimum and maximum blood concentrations of 0.6 and 4.3 mg. per 100 ml. respectively in samples taken 24 hours after administration.

In these doses given normally over a period of 10 days and in no case in excess of 31 days no toxic effects from sulphadiazine were encountered in the 130 patients studied.

We express our thanks and indebtedness for all the help given by the Mairon, Miss E M G Barcham, by the Sisters of the wards, Miss E M Walton, Miss M S Jennings, and Miss R E Lenion, by the nursing staff of the wards and the receiving room, and by the laundry superintendents, Miss E Dudley and her staff. We thank Mr F Courtney Harwood and his staff of the British Launderers' Research Association for their supervision of the laundry oiling. Dr A B Rosher and Dr J P Kennedy for their help and encouragement, Dr E Hardy for making the sulphadiazine estimations, Dr S D Elliott for the use of precipitin typing sera, Dr O M Lidwell and Dr J E Lovelock for measuring the ventilation rates of the wards and the Medical Research Council for a personal grant to one of us (J W).

ADRENALECTOMY IN MENTAL DISORDER

BY

E CUNNINGHAM DAX, MB, BSc, DPM

E J RADLEY SMITH, MS, FRCS

AND

F REITMAN, MD, DPM

(From Netherne Hospital Coulsdon)

Although the endocrines have been largely employed in the practice of psychiatry, on the whole little progress has yet been made towards either improving the patients by their use or elucidating a relationship between glandular disturbances and mental disorders. Moreover, few of the diseases of the endocrine glands or the operative procedures connected with their relief have thrown any definite light on the relationship between psychiatry and endocrinology. At least seven cases of amelioration of mental symptoms following unilateral adrenalectomy have been reported (Allen *et al*, 1939, Allen and Broster, 1945, Greene, Paterson, and Pile, 1945). It would seem equally important to describe two cases with well-marked mental abnormalities associated with characteristic glandular changes which were unimproved by this operation, whilst other findings of some interest have emerged from the investigations.

Case 1

A 44-year-old single woman was admitted to hospital in December 1945. She was in an extremely neglected bodily state and prior to her admission she was treated by the authorities as a person wandering at large. No history was available, and she was unable to give any details of her previous life until after the operation. She was completely apathetic, dull,

retarded, and disinterested. Although she answered questions her replies were monosyllabic and hardly relevant. During the time she was in hospital before the operation she remained apathetic, and she either did not properly appreciate her position or was completely indifferent to it. It appeared that she had some intellectual impairment and at times a mild clouding of consciousness. Her physical state approximated closely to that described by Broster as 'adrenal virilism,' because it seems to have arisen in adult life many years after the development of menstruation and the female secondary sexual characteristics. She was a well-built woman, muscular rather than obese. The outstanding abnormality in the secondary sex characters was that the hair growth was male in distribution. The whole of the beard area—lip, chin, lower cheeks, and pre-auricular region—was covered with long coarse hair, the pubic hair extended up to the umbilicus, the thighs were hairy to a very marked degree. The hirsuties had been noticed for three or four years. The blood pressure was not raised 135/125/95/75. Menstruation had ceased for about two years. The history suggests that the abnormality of suprarenal cortical function did not occur until about the age of 40, so that it was not surprising to find well developed breasts and a female relationship between the respective widths of the pelvic and pectoral girdles. Preoperatively her urinary steroids measured as androsterone were 60 mg in 24 hours (normal 9–12 mg). Her blood sugar (Fig 1, curve A) showed a flat curve of the pituitary

Fig 1—Case 1. Blood sugar curve before operation, A, and after operation, B.

type as found in Broster and Vines's polyglandular type 3. The blood sedimentation rate fell 8 mm in the first hour (200 mm Westergren column). The differential blood count, blood cholesterol, urea, and serum chlorides were within normal limits. Intravenous pnelography did not give any indication of unilateral suprarenal enlargement, and therefore laparotomy was performed in April, 1946. The right suprarenal was much larger than the left. Examination revealed a normal development of the female pelvic organs. When two days before the adrenalectomy, she was told that she was to have an operation in order to lose all her hair growth the only remark she made was 'Rather far-fetched to operate on the tummy to lose hair on my face.' Then she sank back into her apathetic condition again.

In May 1946 right adrenalectomy was performed by Bernard Fey's costo-abdominal approach, which gave an excellent exposure of the suprarenal. Briefly, in the Bernard Fey approach an incision is made along the upper border of the eleventh rib to the tip and continued thence towards the anterior iliac spine in the line of the fibres of the external oblique. The eleventh rib is freed subperiosteally and displaced downwards. The posterior peritoneum is incised the common origin of the diaphragm and transversalis abdominis muscle divided near the tip of the rib, and the transversalis split in the direction of its fibres. This exposes the upper pole of the kidney and leads direct to the suprarenal. Mouat (1939) wrote 'I can find no record of Fey's costo-abdominal route having been used for operations other than those on the kidney and ureter, but inspection of the surrounding structures during operation and my experience of it in the dissecting-room lead me to suggest that this route might with advantage be used for operations on the adrenals or for repair from below of the hiatus in diaphragmatic hernia.' Since 1939 Mr John Everidge has strongly recommended to one of us (E J R S) the use of this route for operations on the suprarenal and whatever its role may be in renal surgery it does appear

give an ideal approach to structures superior to the kidney on either side of the body

The operation was performed without difficulty and the blood loss was small. The patient's pulse was of good volume and between 80 and 90 a minute until the suprarenal was handled while being freed from its surrounding structures. The rate then suddenly rose to 150-160 with extrasystoles, although it was still described by the anaesthetist as a 'good' pulse. The patient did not present the picture of surgical shock in that her colour remained good, she did not become cold, and the blood-pressure reading of 125/75 was little below her pre-operative figure. The injection of desoxycorticosterone, recommended in this operation, did not affect the rapid pulse, which persisted at about 150 for eight hours, after which it fell to 80. This strange reaction in pulse rate without other signs of shock is somewhat different from the results described by Zondek (1945) and others.

She had an uneventful post-operative convalescence. Four weeks after the operation she was slightly more alert mentally, gave a better account of herself, spoke about her mother's death and her solitary life in her own house, and expressed some concern regarding her present financial condition and other difficulties. She said that she lived in a house, which she inherited from her mother, but was entirely alone, the house fell to pieces, the ruins were infested with mice, and the bank clerks told her that she had no money. The next thing she remembered was that the authorities sent her to hospital. Her mental improvement did not materially progress after this although she showed increased interests and was moderately sociable. She could not, however, fully appreciate her position, she smiled foolishly when asked questions, was hardly employable, lacked interest and initiative, and seemed to be indifferent to the operation and her future. She appeared to have a slight loss of her facial hirsutism.

Two months after the operation she asked whether she could be allowed to go out for short walks in the grounds as she felt bored. This was permitted, and on the first day she absconded. She was, however, readmitted three weeks later. When outside she was living in the ruins of her home, and as she did not have enough to eat she raided the pig-bins of the neighbours for food.

Four months after the operation it appeared that little if any hair had fallen out spontaneously, but there was the 'painless depilation' described in adrenal virilism. The long coarse hairs on the beard area could easily be plucked out without pain. The absence of complaint could not be ascribed to her mental condition, as she showed obvious signs of pain when a hair of the eyebrow was pulled out, and stated that it hurt. Also, the beard hair came out easily without causing puckering of the skin, whereas it was difficult to avulse an eyebrow, and a cone of skin was drawn up before the hair came out. At this time she was menstruating irregularly, but her breasts and bodily configuration were of course unchanged.

Although the pathological investigations were repeated at weekly intervals the results were constant after the first six weeks. The steroids had fallen from 60 to 8.4 mg of androsterone a day. The blood-sugar curve returned to normal (Fig 1, curve B), the sedimentation rate was increased to 22 mm in the first hour and it still had not changed a month later. Blood chlorides were decreased from 430 to 390 mg per 100 ml. The cholesterol, urea, and differential blood count showed no change. Histologically the excised suprarenal gland revealed very marked adenomatous changes the poncau fuchsin staining was evident, and the cortex was remarkably enlarged and of abnormal pattern.

Case 2

A 43-year-old single woman, a typist, was admitted to hospital on Nov 3, 1944, suffering from schizophrenia. The patient's paternal grandfather had died of senile dementia, he was always peculiar in his ways. The father died when the patient was quite a child. The mother dominated her. She has a normal sister. She was always a shy, sensitive child. When 10 years old she had a motor accident, when she was torn from the front to the back passage. She was in hospital

for a short time. Her mother was constantly talking about this accident, and the patient became very self-conscious of it. She was brilliant at school and read a lot of good literature. As menstruation did not commence her mother insisted on her going to various doctors. Endocrine treatments were given without result, and it was agreed that her delayed maturity might be due to psychological shock. Meanwhile she started work, and on the encouragement of her sister she left home and lived independently in lodgings. She was then obviously in a 'nervous state' and began psychoanalytical treatment. This however, was unsuccessful, and was interrupted by her progressive psychosis. She became markedly eccentric, a pacifist, a feminist, she gave away her salary to fellow workers and developed an involved teaching on sex theories. Ultimately she became progressively dissociated and had to be admitted to hospital.

One sample of the stream of talk should illustrate her mental state. "I am married to a motor-car since ages. I am as feminine as Elizabeth in Jane Austen's novel. I cannot talk to somebody who is having a stronger personality than I. I did not have sex appeal, but now I am having it. I had a car accident and my sexuality was lost, but I was pictorially guided and retained femininity. My body is feminine. When I do anything I see it pictorially, I saw myself going to school. My sex tells me that the feminine brain is different to the masculine brain. I used to have a male brain, I have been treated by women who always treated me as a male. In the factory where I was working there was a man who was my double. My mother wanted to make me into a man. I can not look into your eyes, a man's eyes magnify everything and overpower everything. I never menstruated. I don't want to menstruate, I stopped it with will power, but I still feel vibrating, the electricity is not where my feminine is, and I cannot bear it. I am vegetarian, a vegetarian can live with a man without having a child and flirting. If I don't eat I don't get sexual." During her stay the mental picture was stationary, she had a full course of electric convulsion therapy without any apparent result.

Physically she corresponded to Broster's type 1, which he calls adrenal pseudo hermaphroditism—that is, a woman in whom changes due to suprarenal cortical pathology arise before puberty and the development of the female secondary sexual characteristics. She had never menstruated. The breasts were not larger than those of a normal man. The hands were broad and bony. She was only of average height, but the pectoral girdle was wide compared with the pelvic. The hair was of male distribution and her upper lip was very hairy, but the whole beard area was not nearly as heavily clothed with hair as in Case 1. Her blood pressure before operation was 130/90.

FIG 2—Case 2 Blood sugar curve before operation, A and after operation, B

The urinary steroids were equal to 20 mg of androsterone in 24 hours. Her blood sugar (Fig 2 curve A) showed an approximately normal curve, her sedimentation rate was 9 mm in the first hour, and the differential blood count, blood cholesterol, urea, and chlorides were within normal limits.

Intravenous pyelography did not reveal any asymmetry, and in April, 1946 laparotomy was performed. This showed that the left suprarenal was larger than the right although the difference between them was not as great as in Case 1. The female pelvic organs were palpated and the uterus found to

be minute. The uterine body was about 1 in (2.5 cm) long and the thickness of an ordinary lead pencil, which suggests that the endocrine abnormality began well before puberty. Five weeks after laparotomy the left suprarenal was removed by the Bernard Fey approach, which again afforded an easy and adequate exposure. The operation was completed without difficulty, and this patient did not show the peculiar behaviour of the pulse observed in Case 1 when the gland was handled, nor any signs of shock.

Four months after operation her physical condition remained unchanged, which is not unexpected, as the adrenal pathology had presumably been in operation for over thirty years, compared with three to four years in Case 1. She was completely indifferent to the operation. Her mental state remained untouched and completely stationary, and her physical condition was unchanged. The operation had, however, produced the anticipated biochemical changes. The urinary steroids had fallen from 20 to 7.4 mg of androsterone six weeks after operation. The blood-sugar curve was normal (Fig 2, curve B), the blood sedimentation rate showed a 22 mm fall for the first hour, the blood chlorides dropped from 440 to 380 mg per 100 ml and remained unchanged after a further six weeks. The cholesterol, urea, and differential blood count values were unchanged. Histologically, the cortex of the excised gland showed some enlargement, but no other change.

Discussion

In the two cases described there is evidence of adrenal dysfunction. This was shown not only by their similarity to other cases that have been found to have abnormalities of these glands but also by their raised urinary ketosteroid excretions. Both had concurrent mental illnesses, and in the first case there seemed to be a definite relationship between the time of onset of the mental and physical symptoms. Neither, however, was notably improved by adrenalectomy.

Theoretically one may postulate a relationship between abnormality of a specific gland and mental illness in the following ways: (1) The mental illness may be the direct result of the glandular dysfunction, (2) the mental illness may cause the glandular dysfunction, (3) the mental illness and the glandular changes may coexist independently, (4) the mental illness may be psychogenic in response to worry over the physical changes induced by the gland, and (5) the mental illness may be the result of secondarily induced changes in other glands. Examples which are largely attributable to one or other of these causes may easily be found, though it is not possible for any one of them to be entirely divorced from the rest.

So far as adrenal abnormalities are concerned primary mental disturbances in paragangliomata of the medulla and in Addison's disease are known, and secondary disturbance due to sexual dysfunction in virilism. Other pathological conditions, however particularly in regard to the various types of hyperadrenalism described by Broster, have not yet been associated with specific mental disturbances, although, as we have said, a number of cases of mental illness have been successfully treated by adrenalectomy. This suggests that the first form of relationship may be fulfilled, but no example of the second is known to have been cited. In regard to the fourth, severe emotional disturbances result from the growth of hair in women, and we have seen a patient other than those described in this paper in whom a very acute anxiety state and definite suicidal ideas developed as a result of her hirsuties. It is possible that some of the less successful results might be explained by the suprarenal overfunction being secondary to pituitary activity, as suggested in the fifth group. Thus an adenomatous gland (adrenal adenomata are common) might conceivably become overactive under undue pituitary influence and its removal might not be

attended by the same relief of mental symptoms as if there was a primary dysfunction.

The first of our two patients developed her mental and physical symptoms at the same time, and it was believed that she belonged to the first group and had every chance of progressing favourably. The urinary androgens were certainly increased before and fell after operation, the chlorides and sugar-tolerance curves became normal, and a tumour giving a ponceau-fuchsin stain on section was removed, yet she did not improve. The second patient, on the other hand, had very long-standing abnormalities, a schizophrenic illness which was coloured by but not necessarily due to the physical changes and polyglandular disturbances. Perhaps, therefore, it was less likely that she would show an improvement after operation. It is interesting that in this case, too, in spite of the suprarenal removal, the reduction in the blood chlorides, the alteration in the sugar curve towards normal, and the post-operative reduction in ketosteroid excretion, there were no mental changes in keeping with this evidence. The raised sedimentation rates which developed subsequent to operation in both cases are unexplained.

Summary

A case of adrenal virilism with mental changes and another of adrenal pseudo-hermaphroditism, also with mental changes are described.

Adrenalectomy (unilateral) produced the expected biochemical effects, and in Case 1 some physical change, but in neither was the mental picture materially affected.

The value of Bernard Fey's approach to the suprarenal is stressed.

A peculiar reaction of the pulse rate, apparently not due to surgical shock, during the removal of a large suprarenal is described.

An unexplained persistent rise in the blood sedimentation rate in both cases is noted.

We are very grateful to Dr W J Griffith, who made the ketosteroid estimations.

MISS RUTH THOMAS is one of those rare people who combine the possession of deep theoretical knowledge and wide practical experience with the power of clear and simple exposition. The seven pamphlets under review are the script of a series of broadcasts and a report prepared for the Curtis Committee. It is high praise to say that they read as well as they sounded. Miss Thomas deals with the early training of the infant and young child in an eminently sensible way, but it is a matter of dispute whether she is right when she forbids "potting" the infant under a year. She is correct in insisting that the child's anal eroticism, which is normal under a year, should not be frustrated and that too early insistence on cleanliness may result in trouble later on, but, by the establishment of a conditioned reflex to the pot, need the child be deprived of its pleasure and would not this save the mother much labour? Miss Thomas's description of the tragedies of homeless children is indeed harrowing, in this respect hell is paved as much by misdirected good intentions as by downright cruelty, and it is a relief to read of the real efforts by the better homes to provide the love and homeliness which these children so sadly miss. This brings out the urgent need for properly training those whose job it is to look after homeless children. These pamphlets should be bought from the National Association for Mental Health (39 Queen Anne Street, London, W) and carefully studied by all those whether medical or lay who are concerned with children and the future welfare of the race. Their titles and prices are: *Children Without Homes How Can They be Compensated for the Loss of Family Life?* (3s 6d) *Fears and Jealousies* (7d), *Children's Fears* (7d), *Children Who Dislike Their Food* (7d), *Further Training Habits* (7d), *Habit Training* (7d) *Temper Tantrums* (7d).

NEUROLOGICAL COMPLICATIONS IN ATYPICAL PNEUMONIA

BY

J MacDONALD HOLMES, MD, MRCP

*Physician, Staffordshire General Infirmary, Consultant
Physician, Wrexham and East Denbighshire War Memorial
Hospital*

During the past few years there have been many accounts of the acute pulmonary infection which is usually called "primary atypical pneumonia." It is now generally accepted that this condition is due to infection by a virus, but attempts to identify a single aetiological agent have so far been unsuccessful. It is probable that many viruses are capable of producing the pulmonary lesions of atypical pneumonia: they have been noticed in influenza, psittacosis, rickettsial infections, and lymphocytic choriomeningitis. The present state of knowledge of the disease has been reviewed by Middleton (1945). Reports in the literature indicate that the mortality rate is low and that the disease usually runs a benign course without serious complications or sequelae. Rarely, however, serious neurological symptoms occur during the course of the disease. The purpose of this article is to describe six cases with such symptoms.

Physical signs of pulmonary disease are usually minimal, and the clinical diagnosis of atypical pneumonia depends almost entirely upon the radiological appearances in films of the chest, which reveal patchy opacities in one or both lungs. These opacities show a streaky increase in density radiating from the lung root and conforming to the general distribution of the bronchi. Superimposed upon this appearance is a mottled type of shadowing which is usually in the lower lobes. Unless serial films are taken during the course of the disease there may sometimes be difficulty in distinguishing the appearances from those of pulmonary tuberculosis. The areas of increased density are as a rule much larger than would be inferred from physical examination of the chest. On rare occasions pleural effusions and multiple fractures of ribs from severe coughing may be seen.

It is probable that much of the increase in recognition of atypical pneumonia in recent years is due to more frequent routine radiological examination of the chest in respiratory infections, particularly in the more benign cases. Little information of diagnostic value is obtained from laboratory investigations. There may be a leucopenia, and many workers have found "cold agglutinins" in the serum, but these features are inconstant and have no specific diagnostic value. The red cell sedimentation rate is usually much increased in the acute stage of the disease, and gradually returns to normal during recovery.

Case Reports

The cases here described include two cases of "acute infective polyneuritis," two cases of lymphocytic meningitis, one of "serous meningitis," and one of encephalitis. In each case the diagnosis of atypical pneumonia was based upon the radiological appearances.

"Acute Infective Polyneuritis"

Case 1—A poultry-breeder aged 65 was seen in consultation with Dr R. D. Neville on Nov. 8, 1944. For a week he had had upper respiratory infection with severe cough, dyspnoea, malaise and pyrexia of 100–101° F (37.8–38.3° C); there was no response to sulphapyridine. On Nov. 7 the patient became confused and irrational and complained of increasing weakness of both legs and inability to pass urine. On examina-

tion signs in the chest were minimal—a few basal rales—although respiratory distress was evident. There was severe flaccid paresis of both legs, and only slight toe movements could be performed. Knee and ankle-jerks and abdominal reflexes were absent, the plantar responses were indefinite. Neurological signs were not seen in the cranial nerves, arms or trunk. Sensory disturbance in the legs was minimal—impaired vibration sense in lower legs and slight loss of position sense in toes. The bladder was distended, and catheterization yielded 25 oz (0.7 l) of urine. The patient was transferred to hospital. Lumbar puncture showed clear cerebrospinal fluid under a pressure of 100 mm, cells 19 lymphocytes per cmm, protein 120 mg per 100 ml, chlorides 710 mg per 100 ml, Lange test, no change, Wassermann reaction negative. On Nov. 9 the patient became more confused and irrational, pyrexia 100–101° F. There were still only scanty signs in the chest and some reddening of the pharynx. A skiagram of the chest revealed characteristic bilateral basal mottling of atypical pneumonia, which disappeared later. Leucocytes numbered 13,000 per cmm (polymorphs 81%). Frequent catheterization was necessary. The mental confusion persisted for a further two days, then subsided. Leg movements began to return, and complete recovery from the flaccid paresis occurred in eight days. The patient was then able to stand, but he still had difficulty in starting micturition. He had full sphincter control three days later. Convalescence was uneventful. He returned home after fourteen days, and has remained well up to the time of writing.

Case 2—A market gardener aged 53 was seen in consultation with Dr F. W. Harrowell on March 1, 1945. He had been ill for about ten days with malaise, high pyrexia, severe cough and respiratory distress. During the previous three days a progressive weakness of the legs and arms had appeared. More recently he had developed difficulty in swallowing, his voice had become hoarse, and he had great difficulty in raising himself from the bed. There was no sphincter disturbance. On examination the temperature was 103° F (39.4° C), respirations 36, and pulse 140. Rales and rhonchi were heard at both lung bases, and there was some injection of the pharynx. The blood pressure was 120/80. There was flaccid paresis of arms and legs. The legs were almost completely paralysed except for slight toe movements. All tendon-jerks and abdominal reflexes were absent, and plantar responses were flexor. There was doubtful loss of position sense in the legs, but no other sensory disturbance. Weakness of the erector spinae, recti abdominis, and intercostal muscles was noted. Respiration was almost entirely maintained by the diaphragm and accessory muscles in the neck. As respiratory paralysis appeared imminent the patient was removed to hospital so that a Drinker respirator could be used, but this was not necessary. Examination of the cerebrospinal fluid showed pressure 130 mm, no cells seen, protein 80 mg per 100 ml, Lange test, no change, Wassermann reaction negative. On March 4 the leucocytes numbered 13,200 per cmm (polymorphs 71%) the pyrexia was subsiding, and there was no increase in paralysis. The temperature became normal in three days. A skiagram of the chest showed basal mottling of atypical pneumonia. The paralysis cleared up very rapidly. On March 10 the patient was able to stand without aid, and thereafter his recovery was uneventful. His hoarseness and dysphagia were cured before the limbs. The tendon jerks had not returned six weeks after his discharge from hospital on March 10, but he has remained well since.

Lymphocytic Meningitis

Case 3—An airman aged 26 was admitted to hospital on April 23, 1943. He had been ill for one day with severe frontal headache, sore throat and dysphagia, pain in the back, and general malaise. There was slight vomiting, and his voice was hoarse. The temperature was 101.4° F (38.5° C), respirations 24, and pulse 72. The tongue was dry and coated, the fauces and tonsils were reddened, with greyish pseudo membrane between the right tonsil and uvula. Klebs-Loeffler bacilli and naemolytic streptococci were not grown from a swab. He was given 16,000 units of diphtheria antitoxin. Next day he was slightly confused and delirious, temperature 102° F (38.9° C). He vomited during the night. The tonsils were still congested and there was profuse nasal discharge. On the 25th the temperature was 102.5° F (39.1° C) and he still had headache.

backache. He resented flexion of the neck, but no definite meningism was present, and no evidence of otitis. Neck rigidity was more definite on the 26th. Cerebrospinal fluid showed pressure, 130 mm, fluid clear, cells, 64 lymphocytes per cmm, protein 90 mg per 100 ml, chlorides 690 mg per 100 ml, culture sterile, Wassermann reaction negative. Next day the readings were pressure 150 mm, cells, 122 lymphocytes per cmm, protein, 100 mg per 100 ml, chlorides 640 mg per 100 ml, culture sterile. The general condition was improved and the headache less, but neck rigidity was still present. On May 3 there was no headache or pyrexia, but he still had sore throat and some cough. The cerebrospinal fluid readings were pressure, 100 mm, cells, 380 per cmm (98% lymphocytes), chlorides, 730 mg per 100 ml, protein 120 mg per 100 ml. A skiagram of the chest on May 5 showed moderate bronchial striation and bilateral basal mottling characteristic of atypical pneumonia. There were no definite physical signs in the chest. The patient was free from symptoms on the 7th, and the cell count had fallen to 12 lymphocytes per cmm. He was discharged to a convalescent unit on May 10.

Case 4—A schoolboy aged 13 was admitted to Wrexham E.M.S. Hospital on March 3, 1945. He became ill on Feb 9 with what was called 'influenza'. Two days later he developed acute pain and tenderness in the left frontal region. After this he developed pain and stiffness in the neck with Kernig's sign and bilateral extensor plantar responses, but no other neurological signs. The cerebrospinal fluid was said to have been normal on Feb 15. On admission cerebation was slow, and he had difficulty in answering questions. Slight neck rigidity and Kernig's sign were present. There were no other neurological signs, no signs in the chest, and no papilloedema. Tachycardia 100 per minute. The cerebrospinal fluid showed pressure, 300 mm, cells, 100 per cmm (50% lymphocytes), protein, 30 mg per 100 ml, chlorides, 680 mg per 100 ml, culture sterile. Leucocytes numbered 9 000 per cmm (84% polymorphs). A skiagram of the chest showed slight thickening of the horizontal interlobe and pleural thickening in the lower part of the left lateral chest wall, with patchy shadowing over the left lower lobe. On March 9 the cerebrospinal fluid readings were pressure, 160 mm, cells 60 per cmm (50% lymphocytes), protein, 60 mg per 100 ml. Further progress was uneventful. A skiagram of the chest on March 26 showed no abnormal shadows in the lung fields apart from pleural thickening at the left base. The patient was discharged on April 23.

Serous Meningitis

Case 5—A man aged 37 was admitted to hospital on Feb 25, 1939. He had had pyrexia of 102–103° F (38.9–39.4° C) for three days with severe cough and malaise, followed by intense frontal headache that was much aggravated by coughing. Only scanty moist sounds were heard in the chest. There was no papilloedema, meningism, or other neurological sign. The nasal sinuses transilluminated well. The cerebrospinal fluid showed pressure, 300 mm, no increase in cells, protein 80 mg per 100 ml, Wassermann reaction negative. He was given 40 ml of 50% dextrose intravenously, with some relief of headache. On Feb 26 the headache was again severe, but it was relieved by further lumbar puncture and intravenous dextrose. The cerebrospinal fluid pressure was still 300 mm. Next day the headache was less severe but there were still no neurological signs. The cerebrospinal fluid showed pressure 250 mm, no increase in cells. A skiagram of the chest revealed characteristic basal mottling of atypical pneumonia. Recovery was rapid and uneventful.

Encephalitis

Case 6—A housewife aged 29 was first seen on Sept 2, 1945, in consultation with Dr O. W. R. Tomkinson. She had been admitted to an isolation hospital on Aug 28 with severe pharyngitis which clinically resembled diphtheria but no Klebs-Loeffler bacilli were found. Pyrexia of 102–103° F (38.9–39.4° C) continued and there was respiratory distress but only scanty rales and rhonchi were heard in the chest. An initial dose of 32 000 units of diphtheria antitoxin had been given and subsequently full doses of sulphathiazole but without satisfactory response. On Sept. 1 the patient became confused and delirious and slight neck rigidity was noticed. Next day the cerebral symptoms were more prominent. The patient

was in a state of irritable stupor, neck rigidity and bilateral extensor plantar responses were present, and the pyrexia was still 102–103° F, but there were no other neurological signs. She was transferred to the Staffordshire General Infirmary, and a lumbar puncture revealed a clear cerebrospinal fluid under a pressure of 160 mm, no cells, protein, 30 mg per 100 ml, culture sterile, Wassermann reaction negative. The pyrexia subsided gradually during the second week of the illness, but widespread rales and rhonchi appeared in the chest and a skiagram showed the characteristic woolly mottling of atypical pneumonia. The meningeal irritation, confusion, and extensor plantar responses disappeared at the end of the second week of the illness. Further skiagrams of the chest showed the gradual disappearance of the opacities. The patient made a complete recovery and was discharged from hospital on Sept 30.

Discussion

Neurological complications in primary atypical pneumonia are undoubtedly rare, but it is probable that in many cases, such as those described here, the severe neurological symptoms may distract attention from the associated pulmonary infection, which may be unrecognized unless skiagrams of the chest are taken. Turner (1945) mentions one case of transverse myelitis in 286 cases of atypical pneumonia. Sheppe *et al* (1943) describe one case of meningo-myelitis in 150 cases. Gundersen (1944) noted one fatal case of haemorrhagic encephalitis in 122 cases, and mentions another fatal case, with cerebral symptoms, which did not come to necropsy. Campbell *et al* (1943) describe one fatal case of encephalitis in 200 cases. Ravenswaay *et al* (1944) noted meningeal symptoms in 0.4% of 1 862 cases, and Glendy *et al* (1945) noted three cases of 'meningism' in 180 cases. Scadding (1937) and Perrone and Wright (1943) each reported a fatal case of encephalitis. Many other reports of large series of cases contain no reference to any neurological complications. Reimann (1938) and Hein (1943) report cases of meningo-encephalitis in which complete recovery took place.

The first two cases described above as 'acute infective polyneuritis' closely resemble those described by Gordon Holmes (1917), Rose Bradford *et al* (1918–19), and Guilmann, Barré, and Strohl (1916). All these authors mention the association of the neurological picture with a respiratory infection, the nature of which at that time was unrecognized. The case of meningo-myelitis described by Sheppe *et al* (1943) was very similar in its clinical manifestations to my two cases of infective polyneuritis, but there was a high cell count in the cerebrospinal fluid, predominantly of lymphocytes. The sensory system was unaffected in their case and was only very slightly affected in my two cases. Another similarity, also mentioned in the earlier accounts, was the very rapid recovery from a severe flaccid paraplegia.

While it is realized that there is no evidence on which to attribute the above cases to the same infective agent, the presence of similar pulmonary lesions in all of them justifies, at any rate, a clinical correlation. The diagnosis of atypical pneumonia in such cases by radiological examination of the chest may have little value from the therapeutic point of view, but it may be of help in giving a hopeful prognosis. It seems probable from the very infrequent incidence of neurological complications that the virus of atypical pneumonia is primarily viscerotropic, and that when nervous involvement does occur the results are not as severe as in infection with primarily neurotropic viruses.

The clinical symptoms of these cases are comparable to those found in other virus infections of the nervous system, but residual damage has been absent. Although fatal cases of myelitis and encephalitis have been reported they appear to be rare.

Summary

Six cases are described in which symptoms of severe spinal and cerebral lesions occurred in association with pulmonary lesions presenting the radiological appearances of atypical pneumonia. Recovery was rapid and complete. Although the clinical picture was variable it was in each case suggestive of a virus infection of the nervous system.

A review of the literature suggests that the nervous system is rarely involved in atypical pneumonia, but that when this does occur the tendency is towards complete recovery without sequelae.

DEFICIENCY DISEASES IN REOCCUPIED HONG KONG

BY

LYDIA FEHILY, M.D.

Lately L.M.O. (Maternity and Child Welfare), Hong Kong

In a paper entitled "Nutritional Diseases in Hong Kong before the Japanese Invasion" (Fehily, 1945) I described the widespread occurrence of B avitaminosis among the Chinese population in Hong Kong which was undoubtedly due to the high consumption of imported highly milled, and, latterly, long-stored rice. This vitamin B deficiency manifested itself mainly in beriberi, which was the second highest cause of death in Hong Kong in 1940, while maternal B avitaminosis (either latent or manifest) was the cause of infantile beriberi, a disease which often appeared in such an acute and lethal form that the term "human milk intoxication" was suggested for it. Practically no other deficiency diseases were observed before the occupation, isolated cases of vitamin A and C deficiencies, mainly secondary, were encountered in unwanted female infants who were fed only on rice paste.

Absence of Gross Deficiency Diseases

On the reoccupation of Hong Kong the medical officers of the British Military Administration were surprised at the absence of widespread beriberi and pellagra, owing to fishing restrictions gross vitamin A and protein deficiencies were also expected, but these did not materialize, neither was real starvation evident although the population of Hong Kong was obviously in a state of subnutrition. However, on close inspection the signs of chronic and mild vitamin B deficiency, mainly that of aneurine and riboflavin were detected.

It seems that during the Japanese occupation of Hong Kong rice was severely rationed and as soon as old long-stored stocks had been exhausted relatively fresh rice was issued to the population. In addition people ate whatever was available, and centuries-old food fads and prejudices

were thrown overboard. Wherever possible, people grew their own vegetables and kept hens and rabbits, even in flats and cubicles. These practices undoubtedly saved the population of Hong Kong from severe deficiency diseases as well as from starvation.

Extensive Relief Work by the Military Administration

After the reoccupation of Hong Kong the Relief Section of the British Military Administration opened free-food kitchens and unstintingly supplied free rations to charitable institutions and to all under-privileged persons, while the British and Australian Red Cross Societies assisted by issuing Red Cross parcels not only to civilian internees and to prisoners of war and their dependants but also to the sick and needy and to orphans.

Unfortunately, since the liberation of the Colony virtually all the rice available has been highly milled, but it has been rationed and supplemented by fresh Australian wheat flour, which, although highly milled, is richer in vitamin B than highly milled rice, and by blue peas, which are rich in vitamin B. In addition the Military Administration distributed vitamins on a large scale, indeed, the population of Hong Kong became vitamin conscious for the first time in its history. The popularity of vitamins may be judged from the fact that on occasion only vitamins were pilfered when warehouses were broken into.

When I arrived in the Colony six months after the liberation undernourishment had almost disappeared and the population was apparently in good health. Admittedly B avitaminosis was still encountered, but with the return of prosperity some people were able to get expensive highly milled rice on the black market and thus defy the rationing system. In addition the return of Hong Kong residents and the large influx of immigrants (many of these returning residents as well as immigrants were already B avitaminotic) made control of nutrition more difficult. Indeed, during the first nine months of liberation the population of Hong Kong tripled and almost reached its pre-war level, so that eventually the issue of rations had to be restricted to returning residents, and immigrants had to patronize the black market, where they purchased highly milled rice as their staple food. In spite of this the incidence of B avitaminosis in Hong Kong was very low compared with that of the years 1938-41, and undoubtedly its complete eradication could be effected if lightly milled rice (or other high-extraction cereals) became the staple food of the population. It is gratifying to know that the Killearn Nutrition Conference in Singapore last year passed the following resolution: "There should be laws or regulations to prevent the high milling of cereals to a degree dangerous to the health of the public, because high milling not only removes valuable nutrients from the food but also reduces the quantity of food available for consumption." However, owing to present world conditions any rice available for importation into the Colony during the last year was only too welcome.

Vitamin B Deficiency in Infants

Special attention was paid to orphanages, infant welfare centres and milk-distribution centres in order to detect any signs of deficiency diseases. In one founding home with 75 orphans up to the age of 5 years I observed signs of vitamin B deficiency in 27 children. The ocular signs of ariboflavinosis were especially prevalent. 12 children had conjunctivitis of the type described as being common in Chinese in Shanghai (Hou 1940, 1941), and 10 other children had photophobia alone. On entering the infants ward one was surprised to see so many infants with their heads buried in their pillows, while others were doubled

up with their heads between their knees. These ocular symptoms were frequently accompanied by cheilosis, marginal stomatitis, and glossitis, and it is interesting to note that both photophobia and conjunctivitis regularly disappeared after a few days' administration of riboflavin and marmite."

Undoubtedly all these infants were deficient also in other components of the vitamin B complex. Two of them (aged 2½ and 3 years) had beriberi of the adult dry type, one had classical acrodynia ("pink disease"), and one had a pellagroid condition of the skin. In smaller infants these multiple deficiencies manifested themselves in wasting, pallor, rigidity of the limbs and body, gastro-intestinal disturbances (mainly due to decreased tolerance of fat and protein), stomatitis, and glossitis. It seemed incongruous to see pale, pinched infantile faces with blood-red lips and tongue. However, the condition of these infants did not represent the true nutritional state of infants in general, almost all the inmates of such foundling homes are unwanted female babies whose mothers were unable or unwilling to nurse them owing to the nature of their work or the partial or complete absence of lactation. Most of these babies, many of whom were found abandoned on the steps, had been fed mainly on rice paste, and showed signs of severe malnutrition on admission; their treatment was extremely difficult because of multiple vitamin deficiencies and gastro-intestinal disturbances.

In one infant welfare centre 190 out of 1,215 cases (15.6%) showed signs of vitamin B deficiency—B₁ deficiency in 77 cases, B₂ and B₆ (riboflavin) deficiency combined in 110 cases, and manifest signs of ariboflavinosis alone in three cases. Only two infants both entirely breast-fed, out of 1,215 of the new cases were found to be suffering from acute infantile beriberi (human milk intoxication). The nutritional state of infants in Hong Kong cannot be judged by the condition of infants brought to infant welfare centres either, as up to 90% of them require medical treatment, there being no children's hospital or special children's clinics.

Subsequently I examined the children at milk-distribution centres. During the Military Administration these centres were established in hospitals, convents, orphanages, and infant welfare centres for the purpose of overcoming the black market in preserved milk, and children of the district up to 2 years of age were registered and supplied with milk at the controlled price. As they had to be brought to the centres, it was possible to observe the nutritional state of infants of most classes in the community. Out of 2,000 babies examined in one centre, 82 (4%) showed signs of vitamin B deficiency, ariboflavinosis being most evident.

Practically no other deficiency diseases were observed, although the hair growth of some babies about the age of 1 year was noticeably poor, probably as a result of deficiency of first-class protein during the Japanese occupation. One 4-year-old child was brought to the centre on its mother's back, and he was suffering from an acute form of rickets and was unable to walk. However, as none of the other children in this family showed signs of vitamin D deficiency this single case of rickets was probably due to some derangement of the endocrine system.

Outbreak of Scurvy

Quite suddenly in April 1946 scurvy broke out in the foundling home previously mentioned, 12 of the orphans being affected. This outbreak was unexpected, as the infants were supposed to be given ascorbic acid tablets and the other children tinned tomato juice as prophylactic, in addition to a regular supply of fresh vegetables. On investigation however it was found that the children's

diet consisted mainly of cereals supplied by the relief section and tinned foodstuffs provided by the British Red Cross Society. Fresh fruit was not available, while the amount of fresh vegetables (owing to the high cost) was quite inadequate. Consequently another orphanage, which I had not previously visited, was inspected, and it was found that of 188 children between the ages of 5 and 17 years 72 (38%) showed signs of frank scurvy. Here the scurvy must have been of considerable duration judging by a most irregular eruption of teeth (unusual among Chinese in Hong Kong), accompanied by enamel hypoplasia and subsequent caries. Close investigation revealed that the children had subsisted for months on a scorbutic diet consisting mainly of cereals and tinned meat and fish supplied by the British Red Cross. Fresh vegetables were supposed to be provided by the Committee (the orphanage being a Chinese charitable institution), but the amount of money allotted for this purpose was on the pre-war scale. To make matters worse, dried vegetables, being cheaper, were frequently supplied instead of the fresh variety. Thereafter fresh vegetables, ascorbic acid tablets, and occasionally oranges were added to the children's diet, with the result that gingival haemorrhages ceased after two weeks, and five of the children with frank scurvy could be regarded as cured after eight weeks. Unfortunately, owing to the ending of my tenure of office, I was unable to observe the further progress of treatment.

A high incidence of conjunctivitis was also present among these children, all but one child showing signs of vitamin C deficiency had conjunctivitis, while only two children with conjunctivitis were free of any other signs or of C avitaminosis. In contrast to the conjunctivitis due to riboflavin deficiency there was no lacrimation or photophobia—indeed, no subjective symptoms whatever—while the only part of the conjunctivae affected was the palpebral. The symptoms consisted mainly of hyperaemia, thickening, and, in one case only, haemorrhage. The alterations in the palpebral conjunctivae seemed to correspond with those of the discoloured and swollen gums in the condition termed "gingivitis scorbutica", "conjunctivitis scorbutica" would seem to be a suitable term for this manifestation in the conjunctivae.

Sporadic cases of scurvy among Chinese nurses also came under my observation. In all these cases the history was similar, the diet consisted mainly of cereals and tinned foodstuffs. As a result of the increased cost of labour, profiteering, and the devaluation of Hong Kong currency by the Japanese the prices demanded by merchants for all local produce were exorbitant, at one time 1 lb (454 g) of local potatoes cost as much as a 14-oz (388-g) tin of imported corned beef. Foreign exchange for the importation of Californian oranges was obtained by some merchants, but the oranges were cornered by unscrupulous profiteers, who either exported them into China or demanded such exorbitant prices that only the very rich could afford to buy them. Consequently the exportation of oranges was prohibited and prices were controlled, with the result that they could be bought at a reasonable price. In addition the Administration endeavoured to cut out the middlemen's profits, so far as the sale of vegetables was concerned, by taking over their activities, and in order to cut down the prices of fruit and vegetables it imported large quantities from the U.S.A. and Australia.

Great Reduction in Mortality Figures

After one year of British reoccupation the health of the population in general has greatly improved and the mortality figures have been considerably reduced. This is a result of the rationing of cereals, the price control of essential foodstuffs, and, to a smaller extent, the

distribution of vitamins. The number of deaths that occur daily now averages less than 45, in comparison with a daily average of 175 in 1941. As regards infant mortality, it is estimated that for the year 1946 the death rate will be approximately 100, as compared with 327 in 1940 (Annual Report of Director of Medical Services, 1940). The mortality rates for 1941 are not available, nor are the rates for the years of enemy occupation (1942-5). However, the infantile death rate during the occupation must have been very high, owing to the absence of any substitute for human milk and the decreased lactation of mothers suffering from undernourishment. In one foundlings' home the mortality rate of babies under 3 months of age was 100%.

Summary

Before the war in the Pacific severe B avitaminosis was widespread in Hong Kong and manifested itself mainly in beriberi. At that time the exceedingly high infantile mortality was chiefly due to a disease termed infantile beriberi or "human milk intoxication."

After the liberation of the Colony the absence of gross deficiency diseases was observed, although the population was in an evident state of subnutrition.

Extensive relief measures undertaken by the Military Administration are cited.

After six months of reoccupation a nutritional survey of infants was made, and it was found that mild and chronic vitamin B deficiency still existed in the Colony to the extent of 36% in a foundling home, 15.6% in an infant welfare centre, and 4% among the children in the milk-distribution centres. Ariboflavinosis was relatively more evident than before the outbreak of the war in the Pacific. Acute infantile beriberi, or "human milk intoxication," had virtually disappeared.

Practically no other deficiency diseases were observed, although, owing to the exorbitant prices of vegetables and fruit and their consequent substitution by cereals and tinned foodstuffs, there were outbreaks of scurvy in two orphanages as well as some isolated cases among the adult population.

After one year of reoccupation the health of the population has greatly improved, and the mortality rates are reduced to less than one third of those for the years immediately preceding the war.

Medical Memoranda

Fatal Tracheitis after Endotracheal Anaesthetic

It has wisely been urged that anaesthetic disasters should be reported.

In common with many other anaesthetists I have for years kept endotracheal tubes in biniodide of mercury (1 in 1,000 solution), that is, until December, 1944 when I had a fatal case of tracheitis.

CASE HISTORY

A woman of 37 was anaesthetized for myomectomy. She had a history of recurrent aphonia which the ENT surgeons had diagnosed as hysterical, though there was said to be "some thickening of the cords." She was induced with "pentothal," cyclopropane, and a little ether and intubated under direct vision. A size 7 Magill tube was used, which was a moderately tight fit. This had been soaked in biniodide and washed. Anaesthesia was maintained with cyclopropane. In the evening of the following day her breathing became difficult, there was also collapse of the right base. Her temperature was 101° F (38.3° C). Adrenaline was advised and 5 ml (0.3 ml) gave considerable relief. The day after there was again an attack of stridor and dyspnoea with the production of greenish sputum. On the third day after operation the dyspnoea became much worse, though the temperature remained at about 101° F (38.3° C). Tracheotomy was performed with great difficulty, but the patient

succumbed on the 13th. Thick membranous material had been removed during this operation.

At necropsy the larynx and trachea were found to be considerably smaller than usual. There was subchronic inflammation in trachea and bronchi, with superimposed acute changes in trachea, bronchi and lungs.

COMMENTARY

The exact cause of death remains uncertain. At that time, however, a number of patients were getting sore throats after intubation—a fact elicited without any more than the customary amount of post-anaesthetic interrogation. Also, at that time face masks were being cleaned with biniodide after use, and a number of patients had a post-operative rash on the face. This was a painless non-irritating erythema. On its first appearance it was as though the shape of the cushion of the mask had been stamped on the face. This mark spread inwards and outwards until in a few days the whole face was red. It ended, a few days later, in a fine, faintly fawn coloured desquamation. The dispensary reported that the biniodide tablets were the same as usual, and the theatre sister that the solution being made was of the usual 1 in 1,000 strength. The rinsing of the masks and the endotracheal tubes was checked. As there was no new factor in the biniodide was there some difference in the wartime rubber? Was it having some action with, or absorbing, the biniodide? With a view to finding an answer to these questions the following test was carried out.

On the forearms of 30 volunteer patients or colleagues three little patches were fixed: (a) a piece of plain endotracheal tube of war time rubber, (b) a piece of a similar tube that had been soaked in biniodide and well washed, and (c) a small pellet of cotton wool dipped in biniodide and squeezed dry. These were inspected at two hourly intervals for 12 hours. There was one doubtful reaction to the plain rubber, nine to the biniodide rubber and eleven to the biniodide. The amount of solution left in the wool may have been variable. The reaction consisted of a pinkening, in several well marked places, followed in a day or two by fine desquamation.

Although this series is small, it does at least show that there is some change in the rubber after it has been soaked in the solution. Since ceasing to use biniodide—and this is now twenty months—we have had no face reactions at all and not more than the occasional sore throat—certainly no such reaction as in the above case.

I should be interested to know whether other people have had similar experiences, or can cast any light on this one.

I thank Miss M. A. M. Bigby, M.D., M.R.C.O.G. (surgeon in charge) for allowing me to publish this case and Dr. W. Pagel, hospital pathologist for his help and interest.

Shell Fragment Migrating from Kidney and Passed per Urethram after 23 Years

The following case report seems interesting enough to merit publication.

A municipal official aged 61 came into my consulting room on May 28, 1942, and produced for inspection a miscellaneous collection of coins and high-explosive shell fragments removed from his body at various times. Among these was a fragment measuring 1 cm by 0.5 cm by 0.2 cm, which he had passed per urethram in 1938. His history was confirmed by reports and radiographs which he brought with him, and was as follows. While serving as a gunner during the second battle of Ypres in 1915 a "whizz bang" shell exploded close to him and inflicted severe wounds in the left leg and lower chest. He had numerous operations and recovered. Eleven years later, in 1926 he was in London and was examined by Col (now Major Gen.) West. There was an open sinus passing between the eleventh and twelfth ribs to the left kidney, and a radiograph showed three pieces of shell casing in the neighbourhood of the kidney but none lower down. An operation was performed and one fragment removed. In 1928 the remains of the kidney were removed and another fragment was recovered. In 1938, ten years later he passed the third fragment per urethram. A radiograph showed that no fragments remained. As no renal colic preceded the event it is improbable that the ureter was the path of transit. The fragment had apparently travelled down and ulcerated into the bladder.

PHYSICS FOR THE ANAESTHETIST

Physics for the Anaesthetist By R R Macintosh, D.M. F.R.C.S.D., D.A., and William W. Mushin, M.B. B.S., D.A. Illustrated by Miss M. McLarty (Pp 235 illustrated 30s) Oxford Blackwell Scientific Publications 1946

It is incontestable that the modern anaesthetist should have a good working knowledge of applied physiology and applied physics. The former subject is dealt with in most textbooks on anaesthesia, but the latter has been generally neglected. The result is that many a candidate for the D.A. finds to his chagrin that he is quite unable to give an intelligible answer to the simplest question involving elementary physics, the memories of his first-year student days having faded into obscurity.

This book from the Nuffield Department of Anaesthetics at Oxford should therefore supply a definite need, for it explains the physical laws which underlie the design and working of all types of anaesthetic apparatus as well as a great variety of other subjects of interest to the anaesthetist. To take two examples, the importance of large-bore and gently curved connexions is explained as is the reason why an air embolism can occur from a leak in a saline infusion apparatus if the controlling clip is placed above the drip chamber. The principle and applications of the injector and the implications of osmosis and filtration are dealt with much more lucidly than is usually the case.

The style is simple with the minimum of technical terms. The numerous illustrations, many in colour executed by Miss McLarty, are clear without the over-simplification which leads to error. The book can be thoroughly recommended.

DISTURBANCES OF MOOD

Les Dérèglements de l'Humeur By Jean Delay. Preface by Gustave Roussy (Pp 180 No price given) Paris Presses Universitaires de France, 108, Boulevard Saint-Germain 1946

The theme of this book is that alterations of mood depend on the Jacksonian principle of cortical control over the lower cerebral centres. In the opinion of the author the hypothalamus stimulates the 'affective levels' of the individual and the cortex integrates them.

In the first part good clinical descriptions are given of depressions, manias and schizophrenic reactions and the effect of shock therapy upon them. Electric shock therapy is most useful in the depressions. An interesting point which is raised is how far hypochondria, psychasthenia, and true neurasthenia are allied to cyclothymic depressions. The author thinks that if the manifestations of these latter conditions are episodic they may be truly cyclic and will be improved by shock therapy, and in fact this therapy may be itself diagnostic as it has no effect unless the condition is truly cyclothymic. The manias are less amenable to shock therapy but may be tried and sometimes combination of shock with insulin therapy is worth while. Shock therapy—or, better, insulin therapy—is indicated in the schizophrenic conditions, but only 26% to 30% of patients are really benefited.

In the second part of the book the cortico-hypothalamic functions are examined in relation to the hyperthymias (manic depressive states) and the hypothymias (schizophrenic reactions). Clinical manifestations of pathological and experimental lesions of the hypothalamus are described and the effects of drugs and shock on hypothalamic function are studied and it is argued that the action of shock therapy can be explained through the action of this therapeutic measure on the diencephalon. The diencephalon may be regarded as 'the metronome of mood,' but the cortex especially the frontal cortex is necessary for its expression. If excessive instinctive and emotional impulses reach the frontal cortex a state of mania will result. In melancholia there is also an excess of diencephalic impulses, but these are of an inhibitory nature. Both these conditions are therefore hyperthymic and represent an over-excitation of the diencephalon. In schizophrenia there is a diminution of diencephalic influence on cortical function which is therefore not controlled by the instinctive necessity to adapt to life which characterizes diencephalic function hence the withdrawal from reality. The

diencephalon is not therefore the seat of consciousness but may well be the centre responsible for the awakening of consciousness. The cortex in its turn normally controls diencephalic activity, especially as with mental growth the instinctive demands become less insistent and the 'long view' takes precedence.

The thesis presented in this book is both interesting and important. Our ignorance of the true nature of the functional psychoses has been one of the reproaches of psychiatry, and the uncontrolled and empirical use of shock therapy has given rise to serious concern. Anything which will give order to our thought on these subjects is therefore well worthy of serious study.

SURGICAL PATHOLOGY

Pathology in Surgery By Naihan Chandler Foot, M.D. (Pp 511 368 black and white illustrations and 20 in colour £3) London J B Lippincott Company 1946

Chandler Foot is known to all pathologists in this country for his many sound contributions to histo pathology both technical and academic. He has written an excellent book full of useful information skilfully illustrated, and remarkably pleasant to read. It is intended to be a guide to the surgical pathology of those disorders in which operations are carried out or specimens removed for the specific purpose of obtaining biopsies, and it is not too comprehensive in the theoretical considerations of all the aspects of the lesions that are described. No serious attempt is made to explore those pathologic lesions that are seen only at autopsy.

Within these self-imposed limitations the author has left him self space and scope to deal at length with those diseases which are normally treated by surgical methods. Diseases of the breast and the gastro-intestinal tract are therefore dealt with in a more specialized manner than is usual in the average text book of surgical pathology. The skin biopsy and the histology of the excised lymph node have not been forgotten. Debatable problems are discussed with commendable brevity and lucidity. This book will prove to be a trustworthy guide to those who undertake the responsibility of reporting upon the routine surgical histology of a general hospital. It will appeal to surgeons because it is so obviously the fruit of the author's long accumulated experience in answering the questions and dealing with the pathological problems of his surgical colleagues.

PULMONARY TUBERCULOSIS STATISTICAL STUDY

The Prognosis of Open Pulmonary Tuberculosis A Clinical Statistical Analysis By Gunnar Berg (Pp 208 No price given) Lund Hakan Ohlssons Boktryckeri

The investigations into the after-histories of patients suffering from pulmonary tuberculosis in England and on the Continent are reviewed by Dr Gunnar Berg in the opening chapters, and the well-known difficulties of comparing these experiences are discussed. The author, in his series of 6,156 patients over the age of 15 with positive sputum who were resident in Gothenburg, Sweden, during the period 1910-34, is not concerned with the effects of treatment upon prognosis as were the majority of earlier workers but takes as his datum line the first appearance of tubercle bacilli in the sputum.

The data obtained from the records of twelve different hospitals and institutions have been analysed by age and sex for the three periods 1910-19, 1920-27, and 1928-34. The mortality was lower in the last period than in the earlier periods for the younger ages and for the first year after contracting the disease, but for the older ages and for cases of four or more years' standing there was little difference in the experiences of the three periods. These differences may be due to some selection of patients; it seems probable that the chance of surviving has not materially altered during the past thirty years. That the data are heterogeneous is a possibility that the author has not sufficiently realized, and this factor may account for some of the apparent differences—e.g. the median duration of disease before the sputum became positive is given as 29 months in 1934 and 116 months (from the table it should be 105 months) in 1910-11. The tabulation in detail of this large series of cases over a long period forms a useful addition to the material available for the study of the after histories of the tuberculous patient.

REVIEWS

The statistical treatment is somewhat faulty. In a number of tables the expected frequencies have been found on various hypotheses and compared with those observed by the test. This test was not justified in all the comparisons made and should not have been used. The analysis of variance carried out was also unjustified. The author deals at length (34 pp) with the prognosis of collapse treatment and reaches a negative conclusion on the results of such treatment. Data collected from so many sources and over such a long period are hardly suitable for such an inquiry. A comparison of survival rates after collapse therapy and conservative treatment is extremely difficult unless the data can be divided into groups of comparable degrees of severity, and this the author was unable to do.

OBSTETRIC PATHOLOGY

A Textbook on Pathology of Labor, the Puerperium and the Newborn By Charles O. McCormick, M.D., F.A.C.S. (Pp 399 illustrated 37s 6d) London Henry Kimpton

This book is based on the author's lectures to senior medical students at Indiana University. One section is devoted to each aspect of the title: labour, the puerperium, and the newborn. The belief is expressed that the attention of the student should be focused upon "infection, toxæmia, hæmorrhage, disproportion, prophylaxis, and diligent attention to the newborn infant." The author also believes that in this streamlining era the symposium type of text becomes a real necessity, so his teaching is arranged in that condensed form beloved of many students on both sides of the Atlantic. It must be remembered, however, that condensed facts are particularly liable to result in indigestion if not taken with due care. The memorizing of lists of summarized facts is not sufficient to turn a keen student into a good doctor. Cause and effect must be correlated logically whenever possible. For example, the pages dealing with uterine inertia contain much sound instruction, but when the treatment of secondary inertia is discussed no reference is made to the fact that this treatment, to be effective, must depend on the cause of the inertia. Lists of symptomatic treatment may be dangerous. The views of the author on sterilization would be regarded as lax in many clinics. Several pages are devoted to descriptions of various techniques which may be adopted when the operation is performed.

The second section of the book deals with the pathology of the puerperium and opens with an excellent account of puerperal infections. Due reference is made to the work of Semmelweis, Oliver Wendell Holmes and Sir Thomas Watson and in the pages referring to these men one catches a glimpse of what a stimulating teacher the author must be. One would imagine that his lectures and ward rounds are enlivened by the crisp phrase and the timely aphorism to drive home the moral of sound doctrine. The book is well illustrated, and in spite of its streamlining has earned its place as a book of reference on this reviewer's bookshelf.

SIR HENRY BASFORD'S new book, *Fisherman's Progress* is published by Constable and Co at 8s 6d. Why do so many doctors discover themselves born fishermen? Probably because the arts of medicine and angling equally demand natural aptitudes for observation, reflection, and manual skill. The author of this little book has also the gift of words to take us to the rivers and lochs he loves so well and lets us share with him the thrill of his first salmon, and the excitement of the huge trout half seen in the darkness and lost after an hour's play. There is no better recreation for the true fisherman when he cannot be by the water than to read books about fishing and this, with its exquisite photographs is perfect of its kind.

A very practical and well illustrated pamphlet, *Infestation Control Rats and Mice* has been published for the Ministry of Food by H.M. Stationery Office at 1s 6d. This handbook, prepared by Mr S. A. Barnett makes generally available to all responsible for the destruction of these pests methods based on rigorous scientific research and tested in large scale practice. Sound and logical planning, in accordance with the general principles laid down by the Ministry, is essential for scientific destruction. The fundamental research on which the methods are based has been carried out under the aegis of the Agricultural Research Council by the Bureau of Animal Population University of Oxford.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Early Ambulation and Related Procedures in Surgical Management By D. J. Leithauer, M.D., F.A.C.S. (Pp 232 \$4.50) Springfield, Illinois Charles C. Thomas 1946

Exercise, especially walking, is regarded as a prominent feature of immediate post-operative treatment. The book includes chapters on psychological factors, pre-operative care, and economic influences.

Sir John Jervis on the Office and Duties of Coroners By W. B. Purchase, M.C., M.B., B.Ch., D.P.H. Eighth edition (Pp 350 30s) London Sweet and Maxwell and Stevens and Sons 1946

This student textbook, which covers the duties of coroners, has been brought up to date and partly recast in narrative form instead of all the subject matter being dependent upon some part of the Coroners' Acts.

New Human Embryology By Bradley M. Patten (Pp 776 45s) London J. and A. Churchill 1946

Designed as a standard textbook of embryology for medical students. Profusely illustrated. From the University of Michigan Medical School.

The Administration of Health and Physical Education By J. F. Williams, M.D., Sc.D., and C. L. Brownell, Ph.D. Third edition (Pp 483 15s) London W. B. Saunders 1946

This American book is intended for school teachers and administrators. The authors discuss such subjects as school sanitation, physical education, handicapped children, swimming pools, and the cost of health education.

Group Psychotherapy: Theory and Practice By J. W. Klapman, M.D. (Pp 344 21s) London Wm. Heinemann 1946

The principles of group psychotherapy are explained. A historical and anthropological summary is followed by an account of group transferences and formations, group and individual psychotherapy, and the use of the psychodrama.

The Nation's Food Edited by A. L. Bacharach, M.A., F.R.I.C. and T. Rendle, C.B.E., F.R.S. (Pp 349 18s) London Society of Chemical Industry 1946

Articles by 32 contributors on the physical and chemical character of British foods, with special reference to nutritional value. The foodstuffs considered are grouped into 7 sections: the egg, the potato, vegetables, cereals, meat, fish, and milk.

Allergy By E. Urbach, M.D., F.A.C.A. and P. M. Gottlieb, M.D., F.A.C.A. Second edition (Pp 968 70s) London Wm. Heinemann 1946

New sections in this book are on psychosomatic aspects of allergy, the Rh factor, allergic bronchitis, allergic cough, and eosinophilic erythrocytæmia.

Tuberculosis in the United States US Public Health Service (Pp 190 No price) US National Tuberculosis Association 1946

Mortality from tuberculosis in the United States presented in the form of statistical tables and maps.

Le Syndrome de Volkmann By M. Chuzaric and F. Junot (Pp 98 115 francs) Paris Masson 1946

A monograph on Volkmann's contracture. Pathative and radical treatments are discussed as well as various theories of the pathology.

L'Hypofonctionnalité By Max Wallet (Pp 354 480 francs) Paris Masson 1946

A study of the physical and mental effects of the excessive production of ovarian hormone. Includes extensive bibliography.

Diagnostic Hormonal et Traitements Hormonaux en Gynécologie By C. Beclere (Pp 371 525 francs) Paris Masson 1946

A book on hormone therapy for practitioners. Includes a discussion on the physiological effects of the pituitary and ovarian hormones.

La Périonite Nodulaire Maladie de Kussmaul By P. Nicaud (Pp 125 255 francs) Paris Masson 1946

A monograph on the symptoms, signs, and treatment of peritonitis nodosa.

La Tuberculose Rénale Sous L'Angle de la Thérapeutique By J. Cibert (Pp 533 1150 francs) Paris Masson 1946

A monograph on the pathology, signs, symptoms, and treatment of renal tuberculosis. Many illustrations.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 8 1947

CONTROL OF MEASLES

After a temporary dislocation in the early years of the war measles has again assumed its biennial periodicity, and we are now on the crest of the epidemic wave of 1946-7, with notifications of over 10,000 per week. But measles, like the other childhood fevers, has steadily lost ground as a killing disease during the past half-century, with an accelerated decline in the death rate since 1920, so that the total deaths now number less than 1,000 in an epidemic year, and the case fatality is reckoned around 0.2%. This remarkable reduction in mortality is probably attributable mostly to improved environmental conditions and the better nutrition of young children, but partly, according to Butler¹ to the delayed age of attack associated with smaller families and partly, no doubt, to the more successful treatment of secondary bronchopneumonia with, for example, the sulphonamides. While mortality has so strikingly declined morbidity remains unaffected, and probably not more than 10% of children in an urban community escape an attack of measles. A recent analysis² of notifications according to age shows that incidence is highest among children aged 3-4 years and next highest among children between 1 and 3 years of age. Most of the serious complications and deaths occur among these younger children, and consequently our efforts should be directed principally towards their protection.

Methods of control may be considered under measures to be adopted in the home in the day or residential nursery, in the school and in the hospital. Perhaps the most important single measure is not so much putting the child to bed as soon as the infection is diagnosed as keeping it there until recovery is complete, with sulphonamide therapy whenever there are signs of secondary complications such as bronchitis or otitis. When, as frequently happens, measles is brought into the home by a child at school, younger children should if possible be passively protected by an injection of convalescent measles serum or normal adult serum. A procedure to be recommended is to give complete protection to the infant between 6 months and 2 years of age by an intramuscular injection of 5 ml convalescent measles serum within five to six days of exposure, counting the appearance of the rash in the primary case as the fourth day. For children aged 3-5 years a dose of 5-10 ml normal adult serum will in most cases either protect or give a modified attack according to dosage, potency of the serum and the day of exposure on which it is given. In a healthy child an attenuated attack is preferable since it does not usually lead to complications and it gives the child immunity to further attack, whereas a

child completely protected becomes susceptible again in three to four weeks' time.

In day or residential nurseries a somewhat similar procedure may be followed. It often happens that infants of 6-18 months are kept separate from the older children and if this younger group is intimately exposed it should if possible be completely protected, even though it means repetition of the prophylactic injections if infection is again introduced some time later. However, the supply of convalescent measles serum is very limited, and the nursery doctor may find it expedient to attempt modification of the infection in the younger children—that is, between the age of 6 months and 3 years—by the use of normal adult serum, which is available from most of the constituent laboratories of the Public Health Laboratory Service. Gamma globulin in controlled trials with small supplies sent from America has proved to be at least twice as potent as convalescent serum in the prophylaxis and attenuation of measles. We understand that experimental batches of gamma globulin are being prepared in this country, and no doubt as supplies become available this substance, if equally successful, may replace all other sera for passive protection against measles. Apparently it may have an additional advantage in being free from the risk of producing homologous serum jaundice, but it should in fairness be stated that thousands of doses of convalescent and normal serum have been given to young children without any untoward effects. The young child may be as resistant to homologous serum jaundice as he apparently is to infective hepatitis.

The school is probably the most important community focus for the dissemination of measles, the secondary attack rate of measles among pre-school susceptible children aged 1-5 years, when a primary case is introduced to the home has been estimated at nearly 90%. If, therefore the age of attack of the primary case at school could be postponed from 5-7 years to 8-10 years the younger children in the household would, with present-day small families, have passed the most susceptible age of 1-3 years. Wells, Wells and Wilder³ have shown that the epidemic spread of measles in junior classrooms can be largely prevented by a "ceiling" of ultra-violet light, and controlled studies, sponsored by the Medical Research Council and the Ministry of Health, are now in progress in a number of schools in Southall to test the efficacy of ultra-violet light in preventing the spread of respiratory infections. If the American findings are corroborated the control of measles in schools may make a valuable contribution to the reduction of deaths and complications from this infection.

In recent years many hospital authorities have made increasing provision for cases of measles at the expense of cases of scarlet fever which is now so mild, and of diphtheria which steadily diminishes in incidence. But, as we have previously emphasized,⁴ the nursing of children together in measles wards is not without its attendant dangers of which the most important is secondary streptococcal infection. The respiratory mucosa after attack by the measles virus is very susceptible to bacterial invasion,

and secondary streptococcal infection rates of 50–70% with suppurative otitis media in 10–20% have been recorded in measles wards. Infected dust from bed linen and floors has been incriminated as the main repository of the haemolytic streptococcus in these measles wards, and dust-suppression by oiling floors and bed linen has proved most effective in limiting streptococcal cross-infection.⁵ In this issue (p 209) Begg, Smellie, and Wright report a further controlled trial in the prevention of secondary streptococcal infection by oiling floors and bed linen in a measles ward during the 1945 epidemic. That oiling of the bed linen, done in the hospital laundry with the help and advice of the British Launderers' Research Association, was effective is indicated by the reductions of 80 and 95% of total bacteria and haemolytic streptococci in the air of the oiled ward during bed-making when compared with similar counts in the control ward. However, the streptococcal pollution of the air in the untreated ward was only about one-tenth of that experienced in another hospital during the 1943 measles epidemic, and for this and possibly other reasons latent streptococcal cross-infection remained at a low level, and there were no cases of secondary streptococcal otitis media. This negative finding must not be regarded as a contraindication of dust-suppressive measures, and it is hoped that hospital authorities will arrange further trials of oiled bed-linen in measles wards. Another interesting observation made by Begg and his colleagues was that the prophylactic use of sulphadiazine (daily doses of 0.25–1 g) was associated with very low streptococcal pollution of the air, a low cross-infection rate and a low incidence of heavy nasal carriers of the haemolytic streptococcus. Here again further controlled trials are needed, and the risk of breeding drug-resistant streptococci by chemoprophylaxis must be borne in mind.

These measures for the control of measles and its complications will have no obvious effect on the total incidence of the disease, and experience with diphtheria has taught us that only active immunization will reduce morbidity as well as mortality. Future progress in the control of measles will therefore depend on the successful cultivation of the virus and the preparation of an effective vaccine. Some preliminary steps along this road have already been taken in America, and now with a gradual return to peacetime conditions British research workers will doubtless bend their energies to this difficult task.

THIS YEAR'S INFLUENZA

For some years before 1939 influenza in Britain seemed to have settled into a simple rhythm. There was an outbreak every second year, and these outbreaks were alternately large and small ones, so that the major epidemics came every fourth year. These were mainly outbreaks due to virus A.⁶ Probably unrelated to their long-term periodicity was last winter's influenza B, so far as we know the first outbreak in this country mainly due to that virus. Virus A had not been much in evidence since the winter of 1943–4. Previously, in 1940–1, virus A, instead of

producing the expected epidemic, occurred in mild sporadic infections as a virus of rather low virulence.⁷ Last winter 1945–6, there was no minor outbreak due to virus A, and this made it difficult to prophesy what would occur this winter—a major prevalence, a minor prevalence, or nothing. It is beginning to look as though “a minor prevalence” is the answer.

A heavy incidence of “influenza” has been reported from many schools, particularly in the London area, and this has led to the premature conclusion that the country is on the eve of a major influenza epidemic. This conclusion appears to be remote from the known facts. Sera and throat washings from affected schools and other young communities have been sent for examination to the Public Health Laboratory Service, but not in any unusual quantity. There has been an abrupt increase, however, in the number of specimens of this kind submitted to the laboratories of the National Institute for Medical Research at Hampstead. We understand that virus A has been recovered from a number of outbreaks at certain schools and hospitals. Virus B has not been found.

There is some virus A influenza about in addition to a febrile catarrh of undetermined origin which produces symptoms for some two or three days. Boarding school communities are particularly affected, but the London County Council schools, for example, record no more absenteeism than is usual at this time of the year. The influenza itself is mild in character and certainly no more severe than the virus B influenza of last year. That the mortality is negligible is well shown by a comparison of the deaths from influenza in the 126 great towns over the first four weeks of this year. The figures were 36, 74, 85, and 92, as compared with 123, 165, 174, and 273 in the first four weeks of 1946. A real epidemic is usually associated with a much more sharply rising curve.

The largest of recent epidemics occurred in 1929, 1933 and 1937, and the figures for these years afford no evidence for the belief that a hard winter will prevent influenza epidemics.⁸ The present trend of the deaths from influenza in the 126 great towns during the past few weeks has been following a similar course to that observed in the outbreaks of 1941, 1942, and 1945. In 1941 the deaths continued to rise during the early weeks of the year, and a maximum of 324 was recorded in the seventh week, while in the other two years the deaths never exceeded 90 a week and the heightened incidence was maintained only for a few weeks. All recent epidemics have been restricted to the first quarter, except that of 1939, when the outbreak extended into the sixteenth week. Deaths in the large towns during the past four weeks are less than half the number recorded in the corresponding period of last year. The low number of deaths and the slow increase in the mortality rate during recent weeks do not suggest that the present outbreak will develop into a severe epidemic.

An incidence of a mild disease, particularly on the “under twenties,” was also a feature of last winter's outbreak of virus B influenza both here and in Australia. The present outbreak is equally mild, but even if influenza seems to be changing its character, having a lower incidence

adults and coming upon us rather less frequently, we had better beware of false confidence, as the virus is clearly an unstable and deceitful agent

THE MINISTER ACCEPTS

The resolution of the Representative Body agreeing to negotiate with the Minister of Health "provided that such discussions are comprehensive in their scope and that the possibility that they may lead to further legislation is not excluded" was sent to him last week, and on Feb 1 the Secretary of the B.M.A. received a reply from the Secretary of the Ministry in which he said "The Minister wishes me to say that he has considered the terms of the resolution and will be glad if the Negotiating Committee will resume discussions with him, in the light of that resolution, at their early convenience"

In discussing the position of the Minister in relation to the Association's offer, *The Times* considered that Mr Bevan could not pledge himself beforehand to any new legislation since this would impose an obligation in advance on Parliament, which has only recently approved the National Health Service Act. The essential requirement, *The Times* states, is the resumption of discussions. "Then, if issues should arise which made Parliamentary intervention indispensable, it would be for Mr Bevan and his colleagues in the Cabinet to consider what action might be appropriate." This would seem to provide the answer to those who still think that Parliamentary intervention is constitutionally impossible or unlikely.

The Negotiating Committee meets on Friday (Feb 7) to consider the resolution of the Representative Body and resolutions from the other constituent bodies. The three English Royal Colleges and the Society of Medical Officers of Health advocate negotiation on regulations without any proviso. Of these bodies only the Royal College of Physicians had the opportunity of revising its resolution in terms of that of the Special Representative Meeting, which has been adopted provisionally by the Royal College of Surgeons of Edinburgh, by the Royal Faculty of Physicians and Surgeons of Glasgow, and by the Association of the Honorary Staffs of the Major (Non-undergraduate Teaching) Voluntary Hospitals of England and Wales. The Society of Apothecaries affirms its loyal support of the final decision of the B.M.A., while the Medical Women's Federation states it has no mandate for saying Yes or No.

FOOD FOR INVALIDS

Food rationing for invalids presents many difficult problems for the doctors looking after them and for those responsible for seeing that available foodstuffs are fairly and evenly distributed throughout the community. Recent correspondence in this *Journal* has shown how disturbed many general practitioners are by what they regard as interference with their proper function of looking after sick persons. Elsewhere in this issue we publish correspondence between Sir Edward Mellanby, in his capacity as Chairman of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council, and the Minister of Food, correspondence between the Secretary of the B.M.A. and the Ministry of Food, and a

statement issued from the Ministry on the procedure for dealing with applications for extra rationed foods on medical grounds.

Even those most critical of recent happenings will admit the justice of Sir Edward's claim that the work of his committee during the past seven years under four successive Ministers of Food has been a noteworthy achievement—noteworthy, among other reasons, for the small volume of complaints directed against this branch of the Ministry's work. Sir Edward describes in his letter the general principles which have been followed by the committee and goes on to say "These are hard principles, and the members of my committee, while appreciating their necessity, have disliked applying them." He asks the Minister whether the services of his committee are still required and whether "it is necessary for them to continue to be guided by the same strict principles." In his reply, Mr Strachey, the Minister of Food, asks the committee to continue its work and adds "I do think that when your committee sits in what I might term its function as a court of appeal against its own regulations as applied by my divisional food officers, it might now begin to take a more lenient view of individual applications." The committee will, no doubt, be relieved by this ruling, which is the final outcome of the publicity given in this *Journal* to instances of the application of what Sir Edward has called "hard principles." The reaction of responsible lay opinion is well put in last Sunday's *Observer* in this editorial comment: "When one considers the amount of rations available in the country for emergency, for visitors, and so on, it is intolerable that a man dying in pain should be denied the few ounces of butter deemed necessary by his doctor in order to give him some relief. This kind of administration can only be described as callous bureaucratic pedantry and is utterly offensive to normal human beings. Are we to send our rationed food to the Germans while our own cancer-cases are denied a necessary morsel?"

HEALTH IN HONG KONG

The present position of Hong Kong was recently reviewed by a special correspondent of *The Times*,¹ who urged the importance of "a five-year or ten-year plan for the social and economic development" of this "tiny colony." Large-scale reforms would need to be undertaken from local resources, but outside aid would be particularly valuable in the sphere of health and education. Perhaps the greatest single health problem is that of nutritional deficiency. Up to 1941 Hong Kong enjoyed a relative economic prosperity and freedom from war. Yet its infantile mortality rate, which was 345 per 1,000 live births in 1939, was one of the highest in the world.² Vitamin B, and mainly B₁, deficiencies were widespread and due to the consumption of imported highly milled rice. Vitamin C deficiency was less common and rarely encountered except in association with a deficiency of vitamin B₁. Beriberi was the second highest cause of death in Hong Kong in 1940, and B₁ avitaminosis either latent or manifest in lactating women caused in their infants a form of beriberi so acute and so lethal that the term "human milk intoxication" was suggested for it.³ Ironically enough the Japanese occupation led to some improvements in nutrition. Long-stored stocks of rice were exhausted and relatively fresh rice was issued even though severely rationed. Centuries-old food fads and prejudices were abandoned by a hungry population and people grew their own vegetables and kept hens and rabbits even in flats.

¹ *The Times* Jan 14 1947 p 5

² *British Medical Journal* 1945 2 468

³ *Ibid.* 1944 2 590

Developments since the defeat of Japan and the setting up of a British Military Administration are discussed by Dr Lydia Fehily at p 220 of this issue. One year of British reoccupation has seen a considerable improvement in the health of the population generally, reflected in a steady reduction in the mortality figures. It seems likely that the infantile mortality for 1946 will be approximately 100. There is cause for congratulation here but not for complacency. Dr Fehily shows that mild and chronic vitamin B deficiency still existed in the Colony to the extent of 36% in a home for foundlings, 15.6% in an infant welfare centre, and 4% among the children attending centres for milk distribution. "Human milk intoxication" had virtually disappeared, but ariboflavinosis was more evident than in earlier surveys.

But much remains to be done. Some such plan as *The Times* suggests will, if it is to be effective, need all the assistance that can be given from both official and voluntary sources. No official policy has yet been defined, but it is significant that the Nutrition Conference in Singapore, presided over by Lord Killearn, recommended that "there should be laws or regulations to prevent the high milling of cereals to a degree dangerous to the health of the public". The British Red Cross Society did much valuable work during the years of occupation and immediately afterwards, and it is not likely that its work will diminish. It is good to know, too, that the Hong Kong Branch of the British Medical Association is again active. At its meeting last week the Council of the B.M.A. approved the urgent requirement of a financial grant to enable the Branch to make good the equipment lost during the Japanese occupation.

WORLD FOOD COUNCIL

Ending malnutrition throughout the world requires the solution to two basic problems: more foodstuffs must be grown, and the poorer nations must increase their purchasing power. Before the war local excesses of foodstuffs commonly occurred in the producing countries, especially in the New World, the undeveloped countries, whose people lacked the purchasing power conferred by industrialization, were powerless to relieve the malnutrition that assailed them. Farmers burnt their wheat where it stood, and planters spilt their coffee beans into the sea.

In September, 1946, at the conference held at Copenhagen by the Food and Agriculture Organization (*Journal* Sept 7, 1946 p 334) Sir John Boyd Orr proposed the setting up of a world food board to stabilize food prices and establish reserves. Most countries including Britain considered that the expense of implementing this scheme would be prohibitive. The Preparatory Commission of the F.A.O. therefore worked out an alternative, and they have now issued their Report. The Commission took the realistic view that agreement between governments is the fundamental necessity, and that the basis of international arrangements should be the expansion of consumption, not the restriction of output. It also reiterated the need for industrial development in backward regions. The most important proposal, however, is the establishment of a World Food Council, whose functions would be to supervise the accumulation of basic food reserves by individual nations, particularly the food producers, and of buffer stocks of commodities subject to seasonal or cyclic variations. The food reserves, though held nationally, would be used internationally in times of famine. The financial arrangements necessitated by such a scheme imply that each country must have a sound economy, so that international credit may be obtained through various channels,

such as the International Bank for Reconstruction and Development.

The Commission's scheme may be seen, therefore, as inspired by Sir John Boyd Orr's proposals but restricted by the nationalism that is still one of the most potent causes of wariness in world affairs. The World Food Council will lack the supra-national power proposed by Sir John for his food board, but its limited scope may commend its virtues more readily to nations determined to retain control of their trading arrangements. Sir John is quoted by the *Observer* (Jan 26) as having said "The world food board was an ideal. This is half-way towards it and will do all that the board would have done if the governments will do their duty."

POSTGRADUATE TEACHING IN FORENSIC MEDICINE

The University of Glasgow will soon be inaugurating postgraduate courses in forensic medicine. These courses are intended for those practitioners whose duties require or would be greatly assisted by, a more extended knowledge of the subject. The provision of these new facilities has been prompted by the fact that continuing study and research has widened the scope of forensic medicine, which should now take its proper place in any scheme for postgraduate education. It is intended to provide a general treatment of medico-legal practice. All the medico-legal activities in the City of Glasgow will be co-ordinated to this end with the co-operation of the university, the Scottish Home Department, the Crown authorities, the corporation of Glasgow, and the chief constable.

The practical outcome of this arrangement will be a liaison between the department of forensic medicine in the university and the scientific bureau of the police, the city mortuary, the city analyst's department, and the sheriff's procurator fiscal. Thus, although remaining under the unchanged control of the police and the corporation respectively, these bodies will co-operate with each other and with the university in activities of common concern and in giving every assistance so far as is consistent with official safeguards in the work of teaching and research. This will include lectures by specialists of the police bureau, practical work in their departments, post-mortem studies and attendance at the various courts to learn procedure and the technique of giving evidence. By permission of the corporation and the Scottish Office, the principal medical officer of the City of Glasgow police is an assistant in the department at the university, and he, with the members of his medical staff, will participate in the general scheme with special regard to the mortuary side of instruction. Such facilities with those already available in the university will lay the foundation for a medico-legal institute in Glasgow. Teaching will be planned scientifically, bearing in mind the need for a higher general standard in the whole range of medico-legal work. Postgraduate instruction will be made available for those who want a "refresher" course and for those who are interested in some special branch of the subject. Courses of short duration will be arranged to meet the individual requirements of those on leave from overseas. Facilities for research will also find a place in the new scheme: one of the important objects of which is the full interchange of knowledge and facilities in the interests of the progressive advancement of new methods and their practical application in the investigation of crime. Arrangements will be made for instructing members of the medical profession who wish to specialize in forensic medicine or who desire to study certain aspects of the subject. Courses will also be

established for senior members of the police and for others whose work demands a knowledge of criminology. Wider scope for co-operation between the medical profession and the police and legal authorities is envisaged by the inauguration of this new scheme at Glasgow.

SUPERIOR VENA CAVAL SYNDROME

Obstruction of the superior vena cava is a subject which lends itself to study by phlebography and measurements of venous pressure. Ehrlich, Ballon, and Graham¹ reviewed the literature in 1934 and collected 309 cases. About 35% were caused by aortic aneurysm, 50% by primary or metastatic thoracic neoplasms, and the remaining 15% by a variety of rare causes, some undetermined.

Hussey² points out that a fistula between an aortic aneurysm and the superior vena cava may lead to the obstruction. Armstrong, Coggin, and Hendrickson³ collected 100 cases of this type of fistula, including two of their own and seven further cases have been reported since 1939. In Hussey's 35 cases there were two examples of the condition and it seems probable that its importance has been insufficiently recognized. In these cases the onset is explosive, with dyspnoea and oedema and cyanosis of the upper part of the body. The diagnosis depends on the sudden onset of severe manifestations of the superior vena caval syndrome in a patient with aortic aneurysm. Signs ordinarily associated with arteriovenous fistula, such as thrill, bruit, and wide pulse-pressure, are not usually found.

Phlebograms were prepared for 13 of Hussey's cases, using diatrizast and thorotrast. Injections were made into a suitable vein in one arm, or simultaneously into both arms, or into the external jugular vein. 20 to 30 ml was injected rapidly through a wide-bore needle. Phlebograms can demonstrate with certainty the presence of an obstruction during life, sometimes in cases in which it might otherwise remain undetected. The level of the obstruction can be shown, and secondary thrombosis extending into the innominate, subclavian, or jugular veins is also revealed.

Venous pressure readings are interesting, and comparison of the pressure in the antecubital and femoral veins is important in diagnosis. The pressure in the antecubital vein should always be significantly higher than that in the femoral vein. The increased volume of blood entering the inferior vena cava by way of collateral vessels is not in itself sufficient to cause elevation of the pressure in the femoral vein and if it is found to be higher than normal some factor other than obstruction of the superior vena cava is responsible. Repeated measurements of venous pressure are valuable for following the course of the syndrome. Lowering of the venous pressure indicates that the collateral circulation has become more adequate or, in the case of a radio-sensitive mediastinal tumour, that the reduction in size of the tumour by x-ray therapy has resulted in a lessening of the obstruction. Hussey states that undue emphasis has been laid upon thrombosis of the superior vena cava and that investigation shows it is rare and is seen for the most part in cases of neoplasm. In malignant cases however it should always be remembered that a sudden onset of severe obstructive symptoms with oedema, cyanosis and dyspnoea strongly suggests that thrombosis has occurred. If this is so it is clear that radiotherapy is scarcely likely to be of benefit. Most patients succumb fairly rapidly to a sudden obstruction of this type. The end is hastened by oedema of the upper air passages and by the high pressure in the cerebral veins, which causes drowsiness, stupor and occasionally convul-

sions and loss of consciousness. In cases of the superior vena caval syndrome phlebography should certainly be made use of, and the method might with advantage be applied more often.

TOTAL PANCREATECTOMY

Total pancreatectomy is an operation which is likely to daunt the most fearless patient and to try the surgical prowess of the operator to the uttermost. The surgeons of the Mayo Clinic¹ are therefore to be congratulated on being able to report success in four cases—one ablation for carcinoma of the head of the gland, one for chronic pancreatitis and two for hyperinsulinism.

The report of the metabolic studies carried out on the patients after recovery from operation is of as much importance as the operative details. From animal experiments intractable steatorrhoea, gross fatty changes in the liver, and severe diabetes were to be expected, but it has been shown that the external secretion of the pancreas is not essential to life, and the internal secretion can be replaced easily. The diabetic state became established within a few hours of operation, but with the striking feature of control by less than forty units of insulin daily. Even the cancerous patient, who had been a diabetic for some years, required only a further twenty units daily. The authors are careful not to make any inference on the aetiology of diabetes from their few cases, but the significance is obvious. All the patients had as many as three large motions daily containing about 30% of the calorie value of the food taken and excess nitrogen and fat residues. All the cases had well-balanced diets containing about 270 g of carbohydrate daily, and fatty livers with hypcholesterolaemia did not develop. It is recommended that all such patients should be given high calorie diets with an abundance of eggs and offals which are rich in choline or other lipotropic substances. The excess of fat and nitrogen in the faeces could be reduced by 40-50% by giving 15 g of pancreatin in enteric-coated capsules daily.

American surgeons are not alone in their interest in this field of surgery, for in 1942 Gordon Taylor² recorded several examples of successful partial pancreatectomy by British surgeons, and in stressing the relatively low malignancy of pancreatic growths he made a plea for the wider use of surgery. Since then cases have been reported by Watson³ and Pannett⁴ for carcinoma and by Oakley⁵ of an almost total pancreatectomy for hyperinsulinism. Pancreatectomy is always likely to have a high mortality in the cachectic cancerous patients, but in hyperinsulinism 80% of adenomata occur in the tail of the gland, and partial pancreatectomy should be tried first. Increasing numbers of successful total pancreatectomies may be anticipated with the aid of vitamin K, blood transfusion and sulphonamides and if the surgical treatment of malignant jaundice becomes firmly established all will be indebted to the present pioneers in this formidable operation.

We regret to announce the death of Dr Arthur Whitfield, Emeritus Professor of Dermatology, King's College, London.

Dr F. Avery Jones F.R.C.P. will deliver the Goulstonian Lectures before the Royal College of Physicians of London, Pall Mall East, S.W., on Tuesday and Thursday March 18 and 20 at 5 p.m. His subject is "Haematemesis and Melaena".

FOOD RATIONING FOR INVALIDS

CORRESPONDENCE BETWEEN THE SECRETARY OF THE B.M.A. AND THE MINISTRY OF FOOD

Dear Sir,

A number of cases have recently been reported by medical practitioners in which their recommendations for additional food allowances to patients under their care have either been rejected by your Ministry, or granted tardily and partially, after what appears to have been an inadequate examination of the medical evidence produced by the practitioners concerned.

These reports have created considerable disquiet among both the medical profession and the public. The Association would therefore be glad to have a detailed statement on how applications for extra rationed foods for individual patients, especially those submitted under Clause 19 of MED 2, are at present being dealt with, both within the Ministry and within the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council.

Yours faithfully,

CHARLES HILL

Jan 7

The Secretary, Ministry of Food

Sir,

In reply to your letter of Jan 7 asking that the British Medical Association may be furnished with a detailed statement about the manner in which applications for extra rationed foods for individual patients, especially those submitted under Clause 19 of MED 2, are at present being dealt with, both within the Ministry and within the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council, I am directed by the Minister of Food to send you the accompanying statement on the subject. I am also directed to enclose a copy of a Question and Answer in the House of Commons on Jan 22 1947*.

I am, Sir,

Your obedient Servant,

D C V PERROTT

Jan 28

STATEMENT BY MINISTRY OF FOOD

Procedure for Dealing with Applications for Extra Rationed Foods on Medical Grounds

(1) No application from a member of the public for extra supplies of rationed foods on medical grounds is considered by the Ministry unless it is supported by a certificate signed by a registered medical practitioner. The only exception to this rule is that certified midwives and health visitors may certify the condition of an expectant mother. A medical practitioner's certificate of his diagnosis of his patient's complaint is always accepted by the Ministry's advisers without question.

(2) The Food Rationing (Special Diets) Advisory Committee¹ of the Medical Research Council has made certain recommendations which are embodied in the instructions issued to all officers of the Ministry who deal with applications made on medical grounds and as far as is necessary, in the Ministry's pamphlet MED 2 which is issued for the information of all medical practitioners.

(3) These recommendations include (a) a schedule of the classes under which extra supplies of milk and eggs may be authorized by doctors (MED 2, paras 1 and 12) (b) a list of conditions which qualify for extra supplies of certain named rationed and controlled foods (MED 2, para 18), (c) a list of commodities, extra supplies of which are not in the opinion of the advisers, required for the treatment of any complaint (MED 2, para 20), (d) a list of complaints for the treatment of which our advisers have considered and advised against granting applications for extra foods other than milk and eggs, and (e) a list of complaints for which certain extra foods may be granted, either outright or pending the final decision of the advisers.

(4) Local Food Offices are required to adhere generally to these instructions but an overriding instruction requires them to refer to higher authority any case in which a doctor insists

that extra foods are necessary for his patient and cases of any type which have not, to the knowledge of the Food Executive Officer, been considered by the advisers. It is also understood by all concerned that in cases of emergency Food Executive Officers may use their discretion in granting extra foods pending a decision being made.

ROUTINE CASES

(5) The procedure in routine cases is for the form R G 30 or medical certificate to be scrutinized on presentation at the Food Office for obvious clerical errors, illegible signatures, and anomalies such as the classification of a patient for extra milk under class 1 (c) without any classification for extra eggs. Queries of this nature are, as far as possible, dealt with immediately and the wishes of the doctor ascertained. Food Executive Officers are required to maintain an up to date list of medical practitioners in their areas for the purpose of applications on which no questions arise are granted immediately and the necessity for speed in arranging for patients to be able to get their extra supplies has been stressed. An instruction requires Food Executive Officers to arrange delivery of priority supplies of milk by telephone if necessary.

(6) Cases which must be referred to higher authority are forwarded immediately, details being given by telephone if necessary, and, when applicable, extra supplies are granted at once either in accordance with the instructions that have been issued or under the Food Executive Officers' powers of discretion.

SPECIAL CASES

(7) Applications for extra foods, or for extra quantities of foods that are not covered by the advisers' standing recommendations and Ministry instructions are all treated as special cases, in addition to any applications which are specifically made under paragraph 19 of MED 2. Food Executive Officers have no powers of decision and the application must be forwarded without delay to Divisional Food Officers. Divisional Food Officers are not empowered finally to reject any application that is supported by a medical certificate but they are informed both by their experience and by information passed on to them by Headquarters of the requirements and views of the advisers and therefore they ensure as far as possible, by reference back to Food Executive Officers or doctors that applications include all the required information. This procedure does, of course, in practice dispose of a number of applications. Divisional Food Officers instruct Food Executive Officers as may be necessary in the exercise of their discretionary powers.

(8) In general all non-routine cases are received at the Headquarters of the Ministry, where the department concerned is in continuous and close touch with the Ministry's advisers through the Ministry's Scientific Advisers' Department.

(9) Since the appointment of the Food Rationing (Special Diets) Advisory Committee in January, 1940 a number of precedents have been established, both on groups of similar cases which have been individually considered by our advisers and on general rulings that have been given.

(10) Applications which are clearly covered by precedent are therefore promptly granted or rejected or if necessary further information is requested. Any case, however, in which there is the slightest doubt whether an exact precedent has been established, cases in which the applicant is dissatisfied with a previous ruling, and of course, all cases specifically made under paragraph 19 of MED 2, are referred to the Scientific Advisers' Department for special consideration by the Food Rationing (Special Diets) Advisory Committee.

(11) The Food Rationing (Special Diets) Advisory Committee advises the Minister on the best disposal of the limited amount of foods available for invalids. In respect of the above special applications referred to them by the Ministry they advise on the priority to be accorded to each on the basis of the statement of the particular case set out in the medical certificate and of the foods available. Applications from England, Wales and Northern Ireland are sent in the first instance to Prof H P Himsforth in London; applications from Scotland to Prof L S P Davidson in Edinburgh. If the application concerns a matter upon which the Committee has already given general guidance a written statement of the reasons for, or against, granting the particular application is prepared and, if agreed to by another member of the Committee forwarded to

* See "Medical Notes in Parliament" *Journal* Feb 1, p 204.

¹ Sir Edward Mellanby (Chairman), Prof L S P Davidson, Sir Francis Fraser, Lord Horder, Dr R D Lawrence, Prof R A McCance, Dr Norman Smith, Prof J C Spence, Prof H P Himsforth (Secretary), Dr M L Rosenheim (Assistant Secretary).

the Ministry of Food. If the application raises a new point it is referred to the whole Committee, advice on the general principle being, if necessary, obtained from professional bodies, or, in the case of unusual illness, from other persons with expert knowledge.

GENERAL

(12) The necessity for the minimum of delay in making or obtaining a decision on every application and in putting the decision into effect has been repeatedly stressed to all concerned.

(13) The Minister accepts full responsibility for the action which is taken in relation to all applications. In practice the Department always accepts the advice which is given and no officer of the Ministry is permitted to adjudicate on the medical evidence given in any case. This does not prevent them however putting into effect the known views of the Food Rationing (Special Diets) Committee, but the principle which has been followed is that all lay officers who handle applications for extra foods on medical grounds do so essentially in the capacity of a Secretariat for the Ministry's medical advisers.

CORRESPONDENCE BETWEEN SIR EDWARD MELLANBY AND MR STRACHEY

Dear Minister

I am writing to you in my capacity as Chairman of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council. As you know this Committee was formed seven years ago at the request of the Minister of Health, the Secretary for Scotland and the then Minister of Food, Mr W S Morrison. Since then this same Committee has functioned continuously under successive Ministers—Lord Woolton, Lord Llewellyn, Sir Ben Smith and yourself—and until the last few weeks there have been few complaints directed against this branch of your Ministry's work. I think you will agree that this is a noteworthy achievement considering the onerous and often invidious duties of the Committee and is in marked contrast to experience in the first European war when invalid and other claims were a major difficulty in working food rationing plans and even at one stage threatened to wreck the scheme. When I have reviewed the hard disinterested and very competent service given by its members and in an outstanding degree by its Secretary, Prof Himsforth and also by Prof Davidson in Scotland I could not help feeling surprised at how little their work was known or understood. There can be few instances in which the work of a whole department of a Ministry apart from routine administrative duties has been planned and carried on for so long by an honorary committee entirely outside the Ministerial organization itself.

The Committee has not only advised your Ministry on thousands of individual appeals against the rationing regulations for invalids on appeals from commercial food interests against restrictions on their supplies given authoritative opinions on requests from industrial bodies and trade unions for special consideration undertaken negotiations with professional bodies on behalf of the Ministry, but it has also entirely devised the present system of invalid rationing down even to its administrative details.

I am sure you will appreciate that the members of the Committee being busy and distinguished men are beginning to wonder how long their services will be required. They appreciate of course that no single medical man could undertake the functions which they now discharge as a body and I as their Chairman may perhaps be permitted to add that I know of no other group of men in this country who have either the status or the knowledge to take their place. Realizing these points and knowing that their duties will not continue indefinitely the Committee would no doubt be prepared to continue but they do feel in need of reassurance on two points.

First, the Committee would like to know if you still desire their services. If so they would appreciate a public statement that the Government has confidence in them. Perhaps you might consider it appropriate to make such a statement in the House when you deal with the matter of invalid rationing. It would certainly be appropriate although I realize it might be impracticable if past Ministers of Food were to associate themselves with such an expression of appreciation.

Secondly, the Committee would like to know whether the situation regarding food supplies is still such that you would

wish them to continue on the same strict principles which were necessary under the exigencies of war. Hitherto such has been the food situation that the Committee has had to formulate its advice in accordance with the following general principles:

(a) That extra rations should only be granted to invalids on the grounds of proven therapeutic necessity,

(b) that extra rations could not be spared for comforts,

(c) that in deciding between competing claims for the limited supplies of food preference should be given to those categories of invalids who are capable of being restored to health or preserved by means of diet, as active workers,

(d) that extra rations should not be granted on vague general grounds, such as debility or general ill health but only when there were precise indications that certain foods were specifically necessary for the patient's treatment,

(e) that only in exceptional cases could the Committee advise you to exercise your prerogative of granting compassionate rations.

These are hard principles, and the members of my Committee, while appreciating their necessity have disliked applying them. As physicians they know that, although the extra rations desired by the patient may be of little or no material benefit to him, the refusal of such rations may cause very real psychological distress. But because of the food supply situation they have had no option in such cases but to advise refusal. Are they to understand that if you still desire their services the food situation is still such that it is necessary for them to continue to be guided by the same strict principles?

Yours sincerely,

E MELLANBY

Jan 9

Dear Sir Edward Mellanby,

Thank you for your letter of Jan 9, to which I hasten to reply.

Let me say at once that I value intensely the work of yourself and your colleagues of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council. I do not see how any Minister of Food could carry on the medical side of food rationing without the help of such a body. As you say it is a unique but exceedingly valuable feature of the present arrangement that an independent honorary committee entirely outside the Ministerial organization itself is responsible for this side of our work. I also agree with you that the present membership of the Committee is authoritative and eminently fitted to perform its duties. I welcome the opportunity to make these views public, which will be given me by a Question put down by Sir Ernest Graham-Little which I shall be answering in the House of Commons next Wednesday, Jan 22. I need hardly tell you that I do desire the continued co-operation and assistance of the Committee. I realize the arduous and self-sacrificing work which it has performed but I must appeal to the Committee to continue to perform its functions while our food difficulties continue.

Finally I come to the points raised by you as to whether some relaxation of the very stringent principles under which the Committee works might not now be permitted. Unfortunately the food situation especially in regard to the particular foodstuffs which I take it are most often recommended such as butter, eggs and meat has not yet improved. In all the circumstances I am inclined to think that we cannot yet make any marked changes in the terms of reference of your Committee. On the other hand I do think that when your Committee sits in what I might term its function as a Court of Appeal against its own regulations as applied by my Divisional Food Officers it might now begin to take a more lenient view of individual applications and I would trust that such a relaxation would help your Committee in its arduous and often unpleasant work.

It is of course still vitally important to prevent a general relaxation in the granting of extra foodstuffs to patients such as did tend to occur this autumn in the case of milk. It would undermine our entire rationing system if it became possible to obtain say double the normal milk ration by means of a complaint to a general practitioner about feeling over-tired or other undefined symptoms.

Yours sincerely

JOHN STRACHEY

Correspondence

Medical Education under the Act

SIR—Among other matters to be discussed with the Minister of Health about the new Health Service should be the payment of medical education for future doctors. It is generally admitted that the sons and daughters of doctors are peculiarly fitted to follow their parents' profession. It is anticipated that there will be a general reduction in the income of general practitioners, and there will also be a loss of capital associated with the buying and selling of practices. It is already a great financial strain on a doctor to educate his children at a university, and unless the Government is prepared at this stage to express the intention of financing the medical education of suitable entrants there will be a great reluctance on the part of the general practitioner to enter the new Service.

There is no suggestion that such grants should be limited to the children of doctors, but open to all suitable candidates. It might be argued that the already expressed policy of the Minister of Education to grant aid where necessary for university education for all purposes will include medical education. This county (Denbigh) has not shown any evidence of its intention to implement the scheme, whereas Glamorgan gives generous grants. Unless these grants are universal there will be difficulty in obtaining doctors to practise in areas where educational facilities are poor.—We are, etc,

TREVOR HUGHES
ENID HUGHES

Ruthin Denbighshire

National Health Service Act

SIR—With the National Health Service looming ahead and the uncertainty throughout the whole profession, it appears a small matter that the Association in the years which lie behind us has interested itself so little in the financial welfare of the country practitioner, particularly such as labour in sparsely populated districts. Here twenty visits may be a hard day's work to visit one panel patient may be half a day's work.

The National Health Insurance pays about £50 mileage for about 500 patients scattered over the hillsides and along broken cart roads, and for dressings, drugs, and dispensing about £60. To such as us the National Health Service can offer nothing worse financially than we already have. Could anyone be surprised if we voted for it? Yet since we elected to labour in the front line of civil practice, with rattling, broken down cars and draughty servantless houses in remote country districts our values must differ from those of the town practitioners. Perhaps we value freedom more highly and when we voted against the National Health Service it was not because of fear of financial loss but because we dreaded to be enmeshed in a colossal Government machine.—I am, etc,

Haydon Bridge Northumberland

RICHARD BELL

SIR—Let us beware before it is too late. We are indeed faced at this very moment with a veritable "medical Munich," which some of your correspondents in the *Journal* of Jan 25 so rightly fear. The Council's resolution of Jan 15 is the first sign of weakening—it is the thin end of the wedge, the Council should adhere to its previous resolution of Dec 11. If we give in now we are lost, when if only the profession would unite, we could so easily win.

We have been accused by the Press of flouting the Government. Surely it is our bounden duty to flout the Government if we think they are guilty of perpetrating evil. Perhaps if more people had flouted the Government and listened to one of our greatest statesmen in the thirties we might have avoided this last war. Many newspapers seem to think it is our duty to collaborate with the Government at all costs yet it was this same Press who suppressed or changed the communications of our foreign correspondents in Berlin before the war, who were trying their hardest to enlighten the people of this country how vigorously the Germans were preparing for war. Are we again to be ruled or swayed by the self-same Press?

The three Presidents of the Royal Colleges have written to Mr Aneurin Bevan. Why, one may ask, did they do this?

Had they a mandate from the profession to do so? Are they not going behind the back of the B.M.A., who have a mandate from the profession and who have decided their policy? They say that a refusal to negotiate may lead to an impasse and they wish to do what they can to prevent such an impasse arising. Sure, those who voted "No" earnestly desire that an impasse should arise, otherwise nothing can change the main provisions of the Act.

Mr Bevan says the Act is law and "within its terms I can negotiate freely." What does this mean? It means that he will not and cannot alter the main provisions of the Act. That is to say he will not and cannot allow the buying and selling of practices. No amount of negotiation can change this. Once we have sold our practices to the Government we become Civil Servants. Why should £66 million of the taxpayers' money be spent on buying up practices in order to abolish the freedom of the doctor without any obvious advantage to the community? Would it not be better to spend this money on research into cancer and tuberculosis and other terrible diseases? All Governments have been niggardly in their grants to research.

Many thinking people are looking to the medical profession to stop this national deterioration that is ensuing from the Government's policy of nationalization at all costs. If we remain united with firm resolve we can do this, as Mr Bevan says no National Health Service Act can function without the full co-operation of the doctors. Mr Bevan has stated his terms. Let us state plainly our terms. We will negotiate with Mr Bevan, nay, we will welcome negotiations with Mr Bevan when, and not until, he abolishes the "five impossible clauses" so aptly named in the *Journal* (Jan 18, p 110) by Dr A. H. Moore—namely (1) Basic salary (2) Refusal to allow an appeal against the Minister's decision in case of dismissal (3) The direction of doctors (4) The most important the refusal to allow the buying and selling of practices (5) The penal clauses—I am, etc,

HUGH TATE

** The day after this letter was written the Representative Body passed the Council's second recommendation.—Ep B.M.J.

The Act and Freedom

SIR—May I say how fully I endorse all Dr Sybil Tremellen says in her letter (Jan 25, p 156)? Is anyone so simple as to imagine that this Government is so concerned about the health of the nation that at all costs this Health Act must be forced upon the country? The health of the country is extraordinarily good considering the privations and hardships we are still subject to. That there is a shortage of hospitals, beds and of staff is well known, but that is the result of the war and labour shortage and has nothing directly to do with the medical profession. No, the real reason is the Government's determination to nationalize the whole country, including the medical profession.

An alarming aspect of the whole thing is the way the trade unions are getting, if they have not already got, control of the Government and this must surely make medical men pause to consider whether they are prepared to place their professional honour and duty to their patients in the power and under the direction of trade union bosses. Anyone who will take the trouble to read K. G. W. Ludecke's book, *I Knew Hitler* will observe the same sinister influences at work—at first, smug benevolence and frothy promises, and then, once the sheep within the fold the whip and curb chain. It is not too late to avoid this tragedy, but we must act together and not waver or compromise over our essential points.—I am, etc,

Burwash Sussex

HOWARD M. STRATFORD

The Plebiscite

SIR—Current professional feeling appears to be a mixture of frustration over the result of the recent plebiscite and hope that in the remaining time before the N.H.S. Act comes into force we may yet see some important modifications. The latter hope however slender, must lead us to an examination of the cause of our failure to express any united opinion in the result of the plebiscite. Undoubtedly this was due in part to the particular form it took, but after a couple of years

working up to the enormous majorities in favour of B.M.A. policy that were obtained at the central meetings it must have been a profound disappointment to many that the profession as a whole did not come forward with the same united endorsement of official policy that it had just given previously to the N.H.I. representatives.

Both in the Government Act and in the B.M.A. "Principles" it is clearly recognized that participation in the future Medical Service is left to the choice of the individual doctor. It therefore follows that both Government and B.M.A. are prepared to leave the final effect of their respective policies to be expressed by the independent decision of each doctor to enter or refrain from joining the Service. That being so a *bloc* of strong united support for any particular policy could only be obtained by the greatest possible decentralization and it was obvious that whereas the Government might hope to achieve final acceptance of their Act without any very large initial acceptance of it by the profession effective opposition could not succeed without a large and firmly united majority. The first step was therefore to ascertain what was the opinion of members of the profession on all important matters relating to the reform of the medical service. For this purpose was issued the now almost forgotten questionnaire. On that should have been founded the official B.M.A. policy. Possibly a further referendum would have been necessary at a later stage, but by such democratic method with a little give and take on all sides there could have been built up a large and united majority which knew for what it fought and loved what it knew. That preliminary reconnaissance was a lot of use to successive Ministers of Health but the pundits of the B.M.A. forsook these democratic beginnings and started what I referred to at the time as a rearranged action by the old guard in a gradual retreat from the *status quo*. Rightly or wrongly an enormously wide front had to be defended when both sides knew that the main body on the B.M.A. side would not be prepared to defend the whole position when it came to the final showdown. By yielding a little ground to the old Conservative regime a tolerable peace might have been signed but that opportunity was lost.

The final phase saw almost unanimous resolutions at B.M.A. meetings in favour of "Principles," which still covered an immense area of opposition to the Government. There was an appearance of democracy but some of us knew only too well that in fact all the support and impetus were centrally generated and that there was still in existence no more reliable index of the reactions of a large part of the profession than was provided by dusty copies of the *Journal* report of the questionnaire. Those who felt that professional and public support should and could be consolidated round the one important issue of ministerial control were swamped at meetings or even jettisoned until the illusion of a united opposition to a number of well known controversial clauses in the Act seemed complete. Knowing that the balance still lay in the hands of a majority whose voice had not been heard since the questionnaire the Government ignored B.M.A. opposition. It must be said that the B.M.A. should not have lost touch with or gone ahead of the rank and file but let it not be forgotten that if a large proportion of the profession was not consulted between the questionnaire and the plebiscite all who failed to come and reveal divergent views and elect their representatives at local meetings must share the responsibility for the creation of this fool's paradise. We might have respected them more if they had forever held their peace instead of breaking silence with their "Yeses" at the plebiscite. All cries and pleadings for unity were in vain because the rallying point was not a natural focus derived and synthesized from the lowest common denominators. In a regime where policy can be carried through as well as formulated by a well supported central junta the B.M.A. which have effected nothing less than a *coup d'etat* B.M.A. whatever may be said for the broad front on which the B.M.A. have stood could never have been effective in a democratic regime until it had so to speak "come to the common front" generally when it had to represent a large number of centres whose own initiative would take them no further than opposition to anything the name "Yes" at the ballot. However, that once "Yes" multiplied comes with it the power of any wholehearted resolutions passed unopposed by a large majority. I can also be the last word when

it comes to voting whether the profession is going into this new Medical Service.

This cannot make pleasant reading to many who have hitherto just looked upward instead of around them, but unless we recognize our weakness we cannot find our strength. Most people can now discern that our true rallying point is round the banner of our freedom. We need not lose that with such rights as the buying and selling of practices. But whatever we lose, if we forgo our own control and administration little else can be retained in the long run. It may be too late but still the only practical course is to go back to the rank and file of the profession and later to the man in the street. A referendum will undoubtedly uncover the real state of affairs in relation to much of our pseudo-united front, but it should also reveal the fundamental basis on which we can unite. We cannot avoid a final showdown and a little anticipation should enable us to formulate some positive amendment of the present Act. If the B.M.A. could not accept the result of the recent plebiscite as a mandate to negotiate with Mr. Bevan are we at present in a position to show Mr. Bevan any valid democratic reason for believing that he has a mandate to tinker with an Act of Parliament that has just passed through both Houses of Parliament? Certainly not. But such a mandate might even yet be forthcoming if we enlisted our democratic power and abandoned methods unsuited to the manner in which all institutions are set up and maintained in this country—I am, etc.,

J. SHACKLETON BAILEY

* This letter was written before the meeting of the Representative Body on Jan. 28.—ED. B.M.J.

An Eighty-four-hour Week

SIR—There is one clause in the Act to which general practitioners should take great exception and that is the one wherein it is stated they will be responsible for all patients at all times. It is generally agreed that there will be a great increase of work, particularly with infants and old people. It is neither in the interests of the patients nor the doctors for the latter to be on duty 168 hours per week and, further, if a doctor contracts to be so responsible he will be unable to fulfil his contract. Who will take his calls when he is out? Domestic servants are scarce and will get scarcer as the years go by. The wives of doctors have enough to do already with their ordinary household duties.

I therefore suggest an 84-hour week. The G.P. will be on duty 7 a.m. to 7 p.m. every day of the week and a night service could be run in each district. With London in mind doctors who could do night duty only could be stationed at the local town hall or any similar convenient building and would receive urgent calls between the hours of 7 p.m. and 7 a.m. I reckon that two doctors and two cars could manage for every 100 doctors in the area. The telephone number could be made popular—say 111 for all districts like 999 except that each district would have its code letters in front of the number. The doctors doing night duty would be young doctors who had done a six-months house job and would then do six months' night duty. The benefit to the general practitioner of twelve hours undisturbed cannot be overstressed.

Finally we have the Press and public against us—Conservative Liberal and Labour—because people have not the imagination to picture a G.P.'s life but when those people, mostly working 40–48 hours per week, read a headline that doctors are demanding an 84-hour week they will appreciate our position and be with us. I have tried this suggestion on several of my patients and have been very gratified at their reactions—I am, etc.,

London S.W. 6

G. ROSEMONT

Food Utensil Bacteriology

SIR—I was most interested in the article on "Food Utensil Bacteriology" by Dr. Irene Hutchinson (Jan. 25 p. 134) as I have felt for a long time that British hygiene standards are very poor. It would be most enlightening to have similar statistics of other countries—say America, Canada and the Scandinavian countries—as a comparison. Surely the public health authorities could do something about the sanit-

arrangements of all feeding places? Why wait for outbreaks of diarrhoea etc., before taking action?

I note that Dr Hutchinson refers to the fact that "no washing facilities were available either within or immediately adjacent to the sanitary convenience." Surely a wash bowl is essential in any sanitary convenience. In many private houses there even seems to be a social snobbery to have a w.c. and a separate bathroom and wash-bowl. I would maintain a wash-bowl essential in a lavatory—separate bathroom if you like. An architect recently discussed a house plan with me in which there was to be a downstairs lavatory and bowl, and even he said, "A bowl downstairs would be regarded as unnecessary, as there was ample accommodation upstairs." What can we do when even our architects feel like that?

As for the lack of soaps, soda and washing cloths, etc., it would seem false economy and the usual incoordination between bureaucratic departments, public health, and Board of Trade or Supply. A further plea on a different line—fuel. Every house has at least one fire inefficiently heating one room whereas with well-designed central heating that one fire burning even poor quality fuel would heat the whole house. An American lady recently said to me she was always constipated in England as our bathrooms and lavatories were so cold that she could not bear to stay in long enough. Is any further comment necessary?—I am, etc.,

Measles and Reconstituted Dried Plasma

SIR—In view of the present epidemic of measles the following case may be of interest to your readers. Four cases of measles were reported on the children's ward of this hospital early in January, and although efforts were made to obtain immunizing serum, these were unsuccessful. It was decided to use reconstituted dried plasma as a method of producing immunity among the remaining children who had not had measles.

Master A., aged 5 years, received 10 ml of double strength reconstituted plasma intravenously one day after exposure to infection. On the tenth day after exposure he had a temperature of 99° F (37.2° C), but was otherwise quite well. Two days after this a Koplik spot was observed and he had a few maculopapules, typical of measles developing fourteen days after exposure. The temperature rose at its highest to 99.6° F (37.5° C). There was no conjunctivitis, cough, or vomiting and the child scarcely felt unwell. An uninterrupted recovery was made.—I am, etc.,

London W 13

R P ARONSON

Haemoglobin Concentration in Lobar Pneumonia

SIR—The article on the "Changes in Haemoglobin Concentration in the Acute Stage of Lobar Pneumonia" (Jan 25, p 131), in which Dr Margaret S Ferguson states that there is no evidence of haemoconcentration in lobar pneumonia, recalls a similar observation made from a different aspect. A few years ago when in hospital we were presented with a case which was either an early lobar pneumonia or an acute abdomen. The haemoglobin was taken and found to be normal. This one would expect to be raised in an acute abdomen and we therefore concluded that we were dealing with pneumonia. The progress of the disease confirmed this diagnosis.

For the next six months the haemoglobin was taken in all cases of lobar pneumonia admitted, and each time was found to be approximately normal. The differential diagnosis of an early pneumonia and an acute abdomen can at times be very puzzling and it is suggested that the simple measure of taking a haemoglobin might be of great assistance.—I am, etc.,

Bradford Yorks

R P MATTOCK

Endocrines in Gynaecology

SIR—The brilliant researches which have led to the isolation of the ovarian hormones and the means of accurately assessing their action are in danger of bringing clinical endocrinology too much into the foreground at the expense of the equally (if not more) important nervous mechanism of control of sexual physiology. So long as conditions are normal Nature leaves

the routine working of the systems which have hormone control to that chemical mechanism. When conditions are abnormal this is far from being the case. In times of great anxiety and stress the nervous controlling mechanism takes precedence over the more slowly acting chemical one, and this action can be instantaneous. Conditions of total war afforded many examples. Frequently the sudden fright of aerial bombardment did cause the menstrual process actually in evidence to cease instantaneously, the nervous tension and anxiety attaching to expected raids did induce the most profound metropathia—to mention the most obvious examples. No gynaecologist would think of attributing these dramatic happenings to abnormal hormone action nor of treating them with hormones.

In civil life the stimuli which affect the autonomic system are less dramatic than those of total warfare and their form is different, they are none the less real and their action is comparable. Those who declare that endocrine therapy is unsatisfactory in the management of the metropathias and the secondary amenorrhoeas should indicate what proportion of their cases are being subjected to this line out of the total number of cases seen. Without this information it is difficult to assess the real value of treatment given—I am, etc.,

Stanmore Middlesex

EVERARD WILLIAMS

SIR—The leader writer (Jan 18, p 96) and Mr Aleck Bourne (p 79) seem to misunderstand the nature of the disease entity metropathia haemorrhagica. This has been isolated from the mix-up of functional bleeding and can be successfully treated by rhythmic substitution therapy with progesterone. The size of the dose and the fact that it may require to be continued for years are irrelevant to the principle of treatment, which is familiar enough in myxoedema and diabetes mellitus.—I am, etc.,

London W 1

DONALD FRASER

Gynaecomastia

SIR—I am surprised to see the recommendation in the annotation under the above heading (Jan 25, p 144) that a surgical removal of the breast tissue should be undertaken in cases of gynaecomastia. During the course of a somewhat long surgical career I have come across many cases of this troublesome little disorder generally in males but occasionally in females, occurring before the true development of adolescence. In every case the condition has settled down after a few months, and a few words of explanation and encouragement are sufficient to allay any worry or anxiety on the part of the patient. I have likewise come across several cases where the small but very mutilating operation of excision has been performed on males and even more unfortunately on females. The operation is wholly unnecessary and should never be undertaken.—I am, etc.,

York

GERALD S HUGHES

SIR—In the annotation on gynaecomastia (Jan 25, p 144) no reference is made to what is perhaps the commonest cause of this condition—leprosy. In the lepromatous or more severe type of leprosy gynaecomastia is a comparatively common complication and the breasts, which are generally both enlarged, may reach considerable size. The cause is supposed to be associated with the destruction of the testicles—a not uncommon occurrence in leprosy. In the most striking case I have seen, in which both breasts were larger than those of a pregnant multipara and were very painful and congested, the administration of thyroid extract gave rapid and complete relief the breasts shrinking to about one third the size in a few days.—I am, etc.,

“Eating well?”

Question that usually gets a wry answer in these days! It's pretty clear that many people are feeling the need of off-the-ration fats and vitamins, because so many of them are taking SevenSeaS. The public is realizing that cod liver oil is a fatty food of high caloric value—the only one available in sufficient quantity to make good the cut in the fat ration, for example. Moreover, it is the only natural source of concentrated vitamins (A and D) which is both home-produced and plentiful.

Luckily, now that our own trawlers have the job in hand again, there is plenty of British cod liver oil for all who need it. There is no shortage of SevenSeaS liquid oil or capsules, and the transport difficulties which sometimes delayed deliveries are straightening out. Obviously the general food rationing situation will be difficult for many months yet. But we hope that the burdens it imposes on doctors and nurses will be somewhat lessened, now that it is possible for anyone to buy this supplementary food from the nearest chemist.

STANDARD OIL Vitamin A 20 000 I.U. Vitamin D 2 500 I.U. per oz
CONCENTRATED Vitamin A 60 000 I.U. Vitamin D 6 000 I.U. per oz

OSTERMILK

made for infants only

Ostermilk is the rational replacement for breast milk when the need arises. Some of the more cogent reasons for advising Ostermilk merit repetition. Ostermilk is a pure roller dried milk food of unvarying composition. It is bacteriologically safe and contains added vitamin D and iron, each in measured useful amounts. Ostermilk is readily digestible giving a light flocculent curd in the stomach. *Two varieties are available both carefully adjusted as to fat and protein content and together providing progressive infant feeding.

When prescribing Ostermilk your co-operation in advising the mother about supplies would be helpful. In her own interests she should ask the chemist to reserve for her the amount of Ostermilk her baby will need calculated from the feeding instructions on the tin. Purchase Ostermilk only through him obtaining at a time sufficient only for current needs. One tin in reserve is sufficient. Whilst supplies of Ostermilk are adequate for the needs of infants up to nine months of age these arrangements will safeguard individual supplies and assist the fair distribution of Ostermilk.

OSTERMILK

*Ostermilk No 1 fat modified for use in the first 3 months
No 2 a full cream food for use thereafter. Both foods incorporate a stated amount of vitamin D and iron.

anaesthesia It has also been the experience of all our ward sisters that patients come round more rapidly and are brighter and thus give rise to far less anxiety to the nursing staff, who welcome the administration of curare for this very reason. As a matter of interest I should like to quote from an article which appeared in *Current Researches in Anaesthesia and Analgesia* March-April, 1946, by Harold R. Griffith who has used curare since 1942: "A judicious use of curare does not seem to increase the hazard of a patient in shock or suffering from haemorrhage, in fact it seems safer to obtain relaxation in this way than to use a toxic anaesthetic agent."

I do not doubt that curare can cause marked respiratory depression. We even know that it can cause respiratory arrest. The point, however, is that this state occurs five minutes after intravenous injection of curare and that even with complete respiratory arrest automatic breathing is resumed within eight minutes. In my own series of over 100 cases I have seen complete respiratory arrest in 5, and each time automatic breathing was resumed in less than five minutes. Controlled breathing was of course performed and there were no after effects in any of these patients. It is therefore obvious that there will be no sign of respiratory depression by the time the patient reaches the ward—usually half an hour or more after the curare has been administered. By that time of course the patient has resumed normal breathing, and furthermore curare is eliminated by the liver and the kidneys within thirty minutes.

The third point in Dr. Massey Dawkins's letter is the occurrence of paralytic ileus. Now, I have personally seen a patient suffering from this condition which came on four days after my anaesthetic of 'pentothal,' cyclopropane, and curare for an abdominal operation. The question of curare being the cause was raised at the time, as is perhaps natural with any fairly new drug. Personally I can see no connexion, nor can I find any mention of this complication in the extensive literature on curare. It is also difficult to see how curare, which is excreted within thirty minutes or so, can possibly cause paralytic ileus four days after the anaesthetic. The only peripheral action of curare apart from its effect on skeletal muscles is a block of the synaptic transmission between preganglionic and postganglionic fibres of the sympathetic nervous system. This would mean constriction of the intestine and active peristalsis, which are certainly not consistent with paralytic ileus—I am etc.,

H. KAHLENBERG

Histology of the Common Cold: An Appeal

SIR—Apart from the work of Hilding (*Arch. Otolaryng.* Chicago, 1930, 12, 133) we have found no references to careful studies of the histological changes produced in man by the common cold virus. Further information about such changes would be of great value in the studies of this disease now being conducted here. Many people are killed in accidents or die acutely from other causes, many people have common colds, especially at this time of year, there must therefore be many who die acutely in the early stages of a cold.

We should be very grateful to any pathologist who could let us have small pieces of nasal mucous membrane from cases of accidental or other acute death where it was known that the subject was in the first week of a cold. Material should be placed in saturated corrosive sublimate solution containing 10% of formalin (40% formaldehyde), and sent to this address. One of us would also be glad to attend personally a necropsy on such a subject, should it be taking place in the London area—We are etc.,

Applications for Special Diets

SIR—In the debate on "Applications for Special Diets," reported in the *Journal* of Feb. 1 (p. 204) Mr. Strachey declared that the Advisory Committee named by him acted as a "court of appeal" to which all disputed cases were individually referred. He thought that its meetings were held weekly and business required and gave an assurance that the average time taken by the committee to decide appeals was nine days.

In an answer a week later (*Hansard* Jan. 29) he said the committee had met twice in the last six months and full meetings are held only when revisions of the schedule are called for. Applications in disputed cases are not dealt with by the committee as a whole but by the secretary, who sends them to the members he thinks most suitable to deal with the particular case. The impressive "court of appeal" is thus whittled down to the exercise of the discretion of the secretary and it is on this authority that the Minister overrules from Whitehall the treatment prescribed by doctors in actual charge of the patients concerned—I am, etc.,

House of Commons

E. GRAHAM-LITTLE

The Food Ration

SIR—With the issue to the fore of the overruling of doctors' recommendations of rationed foods to patients, is it not also more than time that we made our professional voices heard regarding the inadequate rations of good protein and fat? We need no longer be deceived by official statements of world food shortages or by misleading statistics of the quantities of food we consume. Ministers themselves more than hint that rationing is now continued mainly for financial reasons, as such it is the implementation of a policy of suppression and bureaucratic control. Can we honestly deny that physical and mental health would be improved by more liberal allowances of milk, cream, butter, cheese, eggs, and fresh meat and can we reasonably escape the conclusion that the continuation of this low and monotonous level of subsistence, accepted inevitably and even cheerfully during wartime, is contributing in no small measure to the chronic ill-health, frustration, and idleness so prevalent to day?

Patients themselves are aware of this and appeal to the doctor for his verdict on the adequacy of their diet. I submit, Sir, that we should not hesitate to express our considered opinion to patients on this matter, also pointing out in those cases where we would wish to augment diet to assist recovery exactly how and where our hands are tied. Our critical opinion voiced persistently by as many of us who are agreed on this matter, in which the public is so profoundly interested, must surely hasten the loosening of at least this crippling stranglehold on our liberty—I am, etc.,

Kingston Hill Surrey

KENNETH O. A. VICKERY

WAR OFFICE DEMAND FOR JUNIOR OPHTHALMOLOGISTS

The Central Medical War Committee is informed that, because of the shortage of ophthalmologists available for military service, the War Office is prepared to employ as trainee ophthalmologists, with a view to early grading as graded specialists a number of men who, although not at present of graded specialist status, have held resident appointments for not less than six months in ophthalmic hospitals or ophthalmic departments of general hospitals in the United Kingdom, and are recommended by the ophthalmologists under whom they have worked as being competent to deal with errors of refraction, to perform minor operations of the eye and to treat the common diseases of the eye. A large part of the ophthalmic work in the Army falls under these headings, and if men with the limited experience referred to were available to deal with such work, the cases requiring the attention of a fully trained ophthalmic specialist could be concentrated at special centres in the home and overseas commands, greater economy in the use of the specialist officers would thus be effected.

The Central Medical War Committee is now considering the recruitment of young practitioners whose experience in ophthalmology is such as to satisfy the Army's requirements as stated above. It invites applications from practitioners who will shortly complete junior resident appointments in eye hospitals or eye departments and who would like to undertake their military service at this stage as trainee ophthalmologists. Communications should be addressed to the Secretary of the Committee, B.M.A. House, Tavistock Square, London W.C.1.

Obituary

BERNARD T ZWAR, CMG, MD, MS, FRACS

Mr Bernard T Zwar died at his home in Malvern, Victoria, on Jan 16 at the age of 70. Bernard Zwar was born in Adelaide on June 20, 1876, and was educated at Prince Alfred College. He began his medical course in the University of Adelaide, but owing to difficulties at the hospital there about 1897 the students migrated to other universities. Melbourne benefited by the acquisition of Bernard Zwar and Julian Smith, and Sydney by that of Charles Blackburn. These three men were to attain eminence in their chosen professions—Bernard Zwar and Julian Smith as surgeons and Charles Blackburn as a physician.

When he graduated in 1900 Zwar became senior resident surgeon at the Melbourne Hospital, later to become the Royal Melbourne Hospital. He was then, for three years, medical superintendent at the Austin Hospital, where many of the patients were suffering from advanced tuberculosis and malignant disease. He proceeded MD in 1902, and took the MS in 1908 the year in which he was appointed honorary surgeon at St Vincent's Hospital remaining on the staff there until 1911. In 1912 he was appointed honorary surgeon in charge of out-patients at the Melbourne Hospital, where he had been a student and with which he was to be intimately associated for the rest of his life. He remained on the honorary staff of the hospital until 1935, when he was appointed consultant surgeon. In 1937 he became president of the Board of Managers of the Royal Melbourne Hospital and chairman of the Board of the Walter and Eliza Hall Institute.

Zwar served in the Great War of 1914-18 with the rank of major A.A.M.C., as a surgeon in the 2nd Australian Stationary Hospital, and later in the 2nd Australian General Hospital. In 1916 he married Miss Essy Craig and so began the very successful partnership which ended only with his death. Their only son, John, has adopted surgery as his chosen profession and served in the recent war. Zwar was also very closely associated with the University of Melbourne. He was Stewart Lecturer in Surgery from 1924-35, and thereafter became a member of the council of the university, and ultimately Deputy Chancellor in 1943. He was for a long time a member of the Medical Board of Victoria and he took an active part in the formation of the Royal Australasian College of Surgeons, becoming a Foundation Fellow in 1927. In 1929 he was president of the Victoria Branch of the British Medical Association. At the Fourth and at the Fifth Australasian Medical Congresses he was vice-president of the section of surgery.

Dr C H Kellaway writes: My friendship with Zwar dates back to 1912 when I was a resident, and later registrar, at the Melbourne Hospital. Zwar was associated with Mr Moore in private practice and had just become an honorary out-patient surgeon at the hospital. During the time I was in residence he did a great deal of the emergency surgery there. He was a fine surgeon with a first class knowledge of anatomy, and his aseptic technique, in the days when there were some surgeons who had occasional lapses, was beyond reproach. In surgery requiring dissection he was especially skilful. This art he had learnt from Mr Moore—known to us all as Jerry just as Zwar was always known to and addressed by his intimates as 'Z'. He was a splendid teacher and was very good to his young house surgeons whom he would take out to play tennis or to the country in his car at the week-ends.

As a member of the University Council Zwar brought his accurate knowledge of past events his clear and unbiased judgment and his skill in debate fully into play. As president of the hospital he was also chairman of the Board of the Walter and Eliza Hall Institute, and contributed much to developing the Institute and securing its closest possible relationship to the university. His efforts in this direction resulted in the Director of the Institute becoming professor of epidemiology in the university with a university research department within the Institute.

One of the most impressive things about Zwar was his accurate and detailed knowledge of the local history of the profession

of his own hospital of the medical school, and of the university. Among his many activities the work that Zwar did for the Royal Melbourne Hospital stands pre-eminent for he devoted many years of his life to getting the hospital moved from its cramped quarters in the city in Lonsdale Street to the spacious new site in Sydney Road adjacent to the university. This project had many vicissitudes and much opposition and without Zwar's energetic championship it is doubtful whether it would ever have been achieved. Through his personal effort and the enthusiasm he inspired in others he was instrumental in raising a considerable part of the money needed. Much of his time in the last years of his life was spent in hospital and university affairs. As president of the Board of Management of the hospital he saw the new buildings go up the main buildings being finished in time to house the 4th U.S. General Hospital in April, 1942. Finally towards the end of the war and after many delays, Zwar had the crowning satisfaction of seeing completed the removal of the staff and patients from the old hospital to the new. For his work for the Royal Melbourne Hospital and for the community Zwar was appointed CMG in 1941.

It was not surprising that Zwar had many friends. He always enjoyed a joke, even a practical one upon occasions. His robust optimism and unfailing cheerfulness had a stimulating influence on patients and friends alike. He was always full of energy and threw himself with characteristic vigour into his outdoor hobbies walking, golf, and gardening, and, even when over 60, he still played a skilful game of tennis in good company. Although he was a sick man for many months before his death, knowing full well the outcome, he continued to write to his friends cheerful letters full of interest in their doings and with never a reference to his own illness. Zwar would have been a leader in any profession or in any circle by reason of his personality, his ability, his forthright honesty and sincerity, and his determination to be satisfied with nothing less than the best.

Dr FRANCIS ROBERT BRYANT BISSHOPP died on Dec 26 at the age of 87, at Tunbridge Wells Hospital after an operation. Dr Bisshopp took the Cambridge MA in 1887, and after a year at Guy's Hospital qualified MB BCh. He proceeded MD in 1892, and was awarded the MRCP in 1901. Dr Bisshopp had been in retirement for some years. He was latterly consultant physician and had been senior physician at the Tunbridge Wells Counties and General Hospital. He was also consulting physician to the Tunbridge Infirmary. A Fellow of the Royal Society of Medicine and of the Medical Society of London, he had been president of the Kent Branch of the British Medical Association in 1927-8. Dr Bisshopp was a resident at Guy's Hospital after qualifying and held successively the posts of resident physician, house-surgeon and resident obstetric physician. He was a quiet and reserved man, but he always continued his association with a few of his earlier contemporaries.

Dr ROBERT VACHELL DE ACTON REDWOOD died on Jan 3 at Crickhowell, Breconshire at the age of 67. He was born into a Unitarian home at Rhymney, and ultimately became chief surgeon to the Rhymney Medical Aid Society, a position which his father and grandfather had held previously as surgeons to the iron and steel works before they were closed down in 1899. The three succeeding generations had held the post of chief surgeon at Rhymney for a period of 142 years, but the family succession to the practice is now broken. Dr Redwood married a Yorkshire lady, a Miss North who survives him. He was trained at the Welsh National School of Medicine at Cardiff and at St Mary's Hospital and after taking the conjoint diploma in 1903 he went to Edinburgh, where he obtained the Fellowship of the Royal College of Surgeons. He had intended practising as a consultant surgeon in ear, nose and throat work, but settled finally in Monmouthshire practising as general surgeon. He was also medical officer of health to the Rhymney Urban District Council and district medical officer under the Monmouthshire Social Welfare Committee. He was a good sportsman, an accurate shot and a fine cricketer played for Monmouthshire in the Minor Counties Tourney, but of recent years he had to take things easily owing to arthritic trouble. The inhabitants of Rhymney and its neighbours have lost a greatly respected friend and one whose memory will be cherished for years to come, for he was gifted with the personal charm and grace of manner which give the balance of life and to the happy relationship between doctor and

He had been a member of the British Medical Association for over forty years surgeon to the Rhymney hospital for even longer, and he was also the St John's Ambulance divisional surgeon for Monmouthshire

Dr ALFRED HAYES SMITH died at a Bradford nursing home on Jan 6 at the age of 63. Dr Smith qualified M.B. B.Ch., B.A.O. in 1908, and he returned to Dublin to take an M.D. in 1939. He served as a captain in the R.A.M.C. in the 1914-18 war, and apart from this interruption most of his professional life was spent in Bradford. He was honorary physician to the Bradford Children's Hospital and had been honorary secretary of the Section of Diseases of Children at the annual meeting of the British Medical Association in 1924. He had published a number of papers on acquired anaemia in childhood, acute aplastic anaemia, and hereditary telangiectasia. He was a staunch supporter of the Conservative Party and of the Society of Individualists, helping to found the Bradford branch of that society in 1944. Perhaps his last published address was given on behalf of the Society of Individualists and the National League for Freedom to a meeting of the Cleckheaton Rotary Club. Dr Smith put forward a vigorous defence of the moral and spiritual quality of a free medical profession as against any form of State medicine. He was a confirmed opponent of the "closed shop" and of the present National Health Service Act.

Dr W. Sampson Handley writes: Dr Hayes Smith had been a friend of mine for many years. He was a passionate idealist and an individualist. After the death in action in North Africa of his only son, a schoolboy when the war broke out, Hayes Smith found solace for his grief in a determined campaign to enlist public opinion in favour of medical freedom and in opposition to the shackles of State medicine. On Dec 16 last he was assisting at an operation when the patient stopped breathing. Hayes Smith continued artificial respiration unceasingly for three hours until the patient revived. The exertion was too much for him. Subsequently he suffered from increasing precordial pain and an electrocardiogram on Dec 21 indicated coronary thrombosis. After a temporary improvement under treatment he died in his sleep on Jan 6. His life and his death too illustrated the selfless devotion to the interests of his patients which characterized the man.

Dr ALEXANDER ROSE of South Norwood, London, died in Edinburgh on Jan 12. Born in Scotland, he qualified M.B., C.M. at Aberdeen in 1889 and took his M.D. in 1906. He started in general practice in South Norwood in 1891, after acting as registrar at the Central London Throat and Ear Hospital. For nearly fifty-five years he conducted a large practice with amazing energy. In 1939 he had intended retiring but decided to play his part in the war effort. His two partners were called up for service with the armed Forces, and so the latter years of practice put a heavy strain on a man of his years. In 1914-18 Dr Rose worked at the emergency hospital at the Davidson Road Schools. During the recent war he was one of the first local doctors to be attached to the ARP organization in South Norwood. His charming personality and fund of Scottish humour combined with his high standard of professional skill to bring him a wide circle of friends who held him in high esteem and affection. As a relaxation from his work his interests lay in B.M.A. work, bridge and chess. He joined the British Medical Association in 1910 and was a member of the executive committee for many years and chairman of the Division 1929-30. A keen bridge player, he entered many competitions and was a member and president of more than one chess club. He showed the same skill in his hobbies as he did in his work. His sudden death occurred while he was playing chess for Edinburgh.

Dr CHARLES FRANCIS PURCELL PLUNKETT died suddenly in his surgery on Jan 14 at the age of 69. Dr Plunkett had not been well for a few days and had been busy. He had just completed his evening surgery when he was taken ill and died shortly afterwards. Born in Ireland, Dr Plunkett took the L.R.C.P.I. and L.M., L.R.C.S.I. and L.M. in 1903. Soon afterwards he came over to this country and he saw service in Salonika during the 1914-18 war. After his demobilization he practised for some years in the Harehills and Beckett Street district of Leeds. His brother-in-law, Dr A. J. Swanton, is still Leeds City Coroner. Later, however, Dr Plunkett set up in practice at Mitcham Road, Tooting, London, and there he was actively engaged in a busy general practice right up to the time of his death. He did particularly valuable work during the recent war and continued to look after his many patients although he had to evacuate his house, which was damaged, and on another occasion he was himself injured in an air raid. Dr Plunkett was one of the most popular general practitioners in Tooting, and the sympathy of all who knew him will go out to his widow, his two sons, and a daughter.

Dr ERNEST GEORGE SYMES SAUNDERS died on Jan 16 at his home in Devonport. He qualified M.B., C.M. at Aberdeen in 1891 and proceeded M.D. in 1893. Not long after qualifying Dr Saunders, who was born at Exminster, started practising at Devonport and he was on the staff of the Prince of Wales Hospital there for forty-three years. He was consulting surgeon to the hospital at the time of his death and for twenty years he had been honorary surgeon to the Torr Home for the Blind. In recent years he had not been so actively engaged in practice as formerly but he never completely retired. Dr Saunders inherited his love of art from his grandfather, Emanuel Jeffery, a freeman of Exeter and a contemporary of Turner. He was one of the original members of the Plymouth Arts Club and of the Plymouth Society of Artists. His chief interest outside his work, however, was in archaeology. He was the oldest member of the parent society and had been for many years chairman of the local branch of the Devonshire Association. He spent many of his leisure hours searching the Blackhouse, Brickfields, and Roborough for flint implements and other archaeological relics.

The death of Mr HERBERT JOHN GREEN at the early age of 40 has cut short what appeared to be a career of great promise. Mr Green was born at Boyndie in Banffshire where his father was a successful farmer and he was educated at Banff Academy. From there he passed to the University of Aberdeen and graduated M.B. Ch.B. in 1930. He was resident house-surgeon to the Aberdeen Royal Infirmary and afterwards to the Royal National Orthopaedic Hospital, London. In 1932 he settled in practice in Banff and was early appointed to the staff of the Chalmers Hospital. Here he carried out much surgical work of high quality and in 1937 he obtained the F.R.C.S.Ed. Becoming interested in obstetrics and gynaecology, he gave up his practice when he was appointed to the Jessop Hospital for Women, Sheffield, in 1938. Here he worked hard and successfully, and in the following year was made registrar to the hospital and tutor in the department of obstetrics and gynaecology of Sheffield University. He obtained the M.R.C.O.G. in 1940. On the outbreak of war in 1939 Mr Green was called on service as medical officer to the Banffshire R.A. Territorial Unit. He served throughout the war at one time holding administrative staff appointments but for the greater part of service he held surgical appointments in India and Ceylon. He attained the rank of lieutenant-colonel. Just over a year ago Mr Green was demobilized and took up again his appointment in Sheffield where his interest in obstetrical and gynaecological work continued unabated. It seemed likely that he would worthily uphold the reputation of the Jessop Hospital in the future but this was not to be. Mr Green was tall and had a genial disposition which brought him many friends both in Banff and Sheffield. He was held in high esteem by the board and the staff of the Jessop Hospital and was popular among the students who profited by his teaching. He was a careful and conscientious surgeon. He is survived by his wife and two sons.

The Services

Capt (Temp Major) N. C. Welply, R.A.M.C., has been appointed MBE (Military Division) in recognition of gallant conduct in carrying out hazardous work in a very brave manner.

Brig F. R. Sandford, CBE, MC, TD, has been appointed Honorary Colonel 43 (Wessex) Division, R.A.M.C., Territorial Army, in succession to Col G. L. Thornton, CBE, MC, TD, whose tenure of appointment has expired.

The following decorations have been conferred by the President of the U.S.A. in recognition of distinguished services in the cause of the Allies:

Legion of Merit Degree of Commander—Major-Gen. Sir A. G. Biggam, KBE, CB, KHP, Major-Gen. (local) D. C. Monro, CBE, CB, KHS, late R.A.M.C.

Legion of Merit Degree of Officer—Brig (local) E. R. Boland, CBE, R.A.M.C.

Bronze Star Medal—Brig (local) Sir Stewart Duke-Elder, KCVO, Major (Temp) P. M. Turquet, R.A.M.C.

The following appointments and mentions in dispatches have been announced in recognition of gallant and distinguished services in the field:

MBE—(Military Division)—Major T. McLardy, R.A.M.C. Capts R. S. Seagat and S. Ahmed, I.A.M.C.

Mentioned in Dispatches—Major G. O. Gauld, and Capts D. Benson, S. Campbell, D. R. MacPherson, L. D. Stone, and W. J. Street, R.A.M.C., Capt C. S. Singh, Sub D. M. Khan, and Jem W. M. Khan, I.A.M.C.

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL

The Standing Committee on Scottish Bills, Mr MATHERS in the chair, began consideration of the National Health Service (Scotland) Bill on Jan. 28. The Committee agreed to sit on Tuesdays and Thursdays of each week.

On the motion that Clause 1 should stand part of the Bill Col WALTER ELLIOT said the Clause which recapitulated the general purposes of the Bill, had secured the approval of a majority of the House of Commons and therefore the Conservative Opposition could not criticize it. Nevertheless there were questions of emphasis which the Opposition thought it worth while to raise. The Clause defined the object of the Bill to be

"The establishment in Scotland of a comprehensive health service designed to secure improvement in the physical and mental health of the people of Scotland and the prevention, diagnosis, and treatment of illness, and for that purpose to provide or secure the effective provision of services in accordance with the following provisions of this Act."

Col Elliot said the Opposition view was that in the past the people of Scotland had themselves done a great deal to secure the provision of effective health services. The concentration which this Bill sought to centre on the Secretary of State for Scotland might slow up the securing of effective health services throughout the whole of Scotland. Therefore the Opposition would seek to lay emphasis on securing in the Bill provisions which would divert its methods from actual provision of services by the Secretary of State himself and from the danger of over-centralization.

Mr THORNTON-KEMSLEY said subsection 2 of Clause 1 stated that the services should be provided free of charge. This was true in the sense that such services would not be followed by an account. In every other sense they would be far from free. Parliament would provide a very expensive service which would have to be paid for by the taxpayer, the ratepayer, and those who paid National Health Insurance contributions. If the service was to be free of charge for all, then so far as he could see any foreign subject staying in this country who required medical attention or treatment of any kind would be eligible to have that service free. He was not sure that this ought to be provided. He suggested that on the Report stage an amendment could be made to make it clear that the service should be free to British subjects resident in the United Kingdom.

Mr STEPHEN drew attention to the provision in subsection 2 that the services provided should be free of charge except where any provision of this Act expressly provided for the making and recovery of charges. He noticed in the Bill a special reference to provision of dental treatment. He hoped the Minister would cut that out of the Bill and have one treatment for all people.

Mr J S C REID said the point raised by Mr Thornton-Kemsley was important. He assumed that if someone was run over in the street the Secretary of State would take that person into a hospital and treat him whether he was alien or Scots. The second type of person was the one who became ill and required the services of a doctor. Could that person walk round to the nearest doctor on the list and say he needed attention? Did he have to find out whether he was on a list somewhere else in Scotland or England? If so, what happened to him meanwhile? Was any member of the community who happened to be sick while away from home entitled to walk round to the nearest doctor on the list, and was that doctor bound to attend to him? If the doctor was not bound to attend to a person on holiday or an alien this service was not comprehensive. Was an alien or a British subject not resident in Scotland entitled to get the services in the Bill which were not so urgent, such as the provision of spectacles?

Paying for the Service

Mr WESTWOOD said he would take all such points into consideration when dealing with the Regulations and the administration. It had been made perfectly clear on Second Reading that somebody had to pay, but so far as calling in the doctor was concerned and getting the service which the Clause sought to provide that would be free to the individual who required the service. The payment would be met as in respect of less than 5% of the cost from local rates nearly 20% from the National Insurance contribution, and the rest directly from the Exchequer. As for providing treatment to those temporarily in the country, the Government would have to see that treat-

ment to those who required it was given. There would have to be regulations to safeguard the services of the doctors who gave such attention. Experience under the National Health Insurance Scheme of to-day could be turned to good service in dealing with the problems of a comprehensive health service. The word comprehensive meant taking in everything.

Col ELLIOT said he had a troublesome case in mind of an alien temporarily resident in this country who was suffering from a dangerous and infectious disease and because he was an alien had been refused treatment not in Scotland but in England since the passage of the National Health Service Bill. His disease was leprosy. An active leper was walking about an English city because he was not allowed access to treatment. Col Elliot thought that the provision of the Bill did not cover that case. Subsidiary legislation might be needed for such cases. The declaration of Mr Westwood went a good deal further than a statement Col Elliot had received from the Chief Medical Officer for England which was that the policy in such cases was to repatriate the individual. That was an ill advised suggestion for an active disease such as leprosy. In the present condition of Europe it was not always possible to repatriate.

Mr SCOLLAN said the fact that a man with leprosy was walking about and that the present medical services could not deal with the case was the finest argument for a new medical service.

Dr MORGAN said Col Elliot had not been in active practice for some time. Had he been, he would have been aware that the infectivity of leprosy had been grossly exaggerated.

Col ELLIOT replied that Dr Adam had certified the infectivity of this case.

Clause 1 was then ordered to stand part of the Bill.

Health Services Council

On Clause 2 Mr J S C REID moved an amendment to provide that the Scottish Health Services Council whose duty would be to advise the Secretary of State upon matters relating to services provided under the Act, should also be empowered to give advice respecting services which could be provided.

Mr WESTWOOD said he was willing to accept the amendment for the purpose of giving him a more comprehensive health service. The Committee then agreed to the amendment. A similar amendment was made in respect of advice on health services provided by local health authorities.

Cmdr GALBRAITH moved to omit from subsection 3 of Clause 2 words which provided that the Secretary of State should appoint Advisory Committees from persons who were members of the Health Services Council and other persons and should do this after consultation with that Council. Cmdr Galbraith thought that the Secretary of State having appointed the Council should allow it to appoint its own members on the Standing Advisory Committees.

Mr Westwood accepted the amendment.

Mr WATSON asked for an explanation of what was meant by "Advisory Councils" and "Advisory Committees" who were to advise the Secretary of State. He pointed out that the Secretary of State could disregard such advice and take his own line.

Mr WILLIS said it seemed dangerous for the Secretary of State to receive advice from a Health Services Council which in turn received advice from Committees appointed by itself.

Mr WESTWOOD said that apart from the members appointed by the Health Services Council he would appoint all the other members on these Advisory Committees. Such appointments would be made only after consultation with the appropriate bodies. The amendment moved by Cmdr Galbraith was then agreed to.

Power to Withhold Annual Reports

Col ELLIOT moved to omit from Clause 2 subsection 5 the provision that the Secretary of State might after consultation with the Health Services Council withhold from Parliament the annual report from that Council or any part of that report if satisfied that publication would be contrary to the public interest. He said the same issue had already been discussed during the debates on the English Act. He thought the danger of unauthorized disclosure was covered by the Official Secrets Act and that so responsible a committee was unlikely to make disclosures against the public interest.

Mr WESTWOOD said the requirement that the annual report must be published was contained in the Clause but was a rather unusual one. He must have the safeguard which was afforded him by the proviso. If there were some new drug for which fantastic claims were made it would be right that until that drug had been tested the Government should not publish a part of the report dealing with it. Again, the report might include a statement about the increasing incidence of certain diseases. The Department did not wish to create undue alarm and it might be desirable in the public interest that the whole

of the report should not be made public. He resisted the amendment.

Mr MACLAY thought that the Secretary of State would never act on his own decision or even on the advice of his permanent officials concerning the publication of a statement on a particular disease or a new drug. He asked him to be guided entirely in such a matter by the Health Services Council of medical experts.

Mr WESTWOOD said that if he could do nothing except by agreement with the committee set up he would be divesting himself of executive responsibility.

Mr SCOLLAN said those who drew up the report would not be foolish enough to include information alarming to the public. Even if they did, and it was kept out of the published report, a Member of Parliament could elicit the information by a Question to the Minister in the House.

Sir JOHN GRAHAM KERR said the ultimate responsibility for administration under the legislation rested with Parliament and it was wrong that any part of the report should be kept secret from Parliament. The proposal to omit the words which had been challenged was defeated by 33 to 16.

Standing Advisory Committees

On the motion that Clause 2 as amended stand part of the Bill Mr MCLEAN WATSON said it appeared to him that in the Health Services Council some interests were over-represented and others were under-represented. He supposed that the representative organizations which the Secretary of State was to consult when appointing the Advisory Committees were organizations outside those already represented on the Council. Was the Minister satisfied that there was no possibility of a conflict between the Standing Advisory Committees and the Council itself?

Mr WESTWOOD said he had in mind as Advisory Committees a medical, a nursing, a hospitals, a mental health, a dental, and a pharmaceutical committee, and so on. Their advice would be considered as and when it was given. On these bodies it would be possible to include members connected with sectional interests which at the moment might be excluded from the central committee. He also proposed to set up a Highlands and Islands Committee. A Standing Advisory Committee under Clause 2 could report direct to the Secretary of State with the provision that a copy of the report went to the main Council, which could make observations on it to the Secretary of State. There would be consultations with the associations of the local authorities, but in a State service there could not be direct representation from a local authority as such. There would be consultation with the national associations of local authorities in Scotland. In appointing an Advisory Committee on nursing he would consult the bodies which controlled nursing in Scotland. For a medical Advisory Committee he would have consultations with the representatives of the British Medical Association. He was prepared to see whether something further could be provided for safeguarding the rights of local authorities.

Clause 2 as amended was then ordered to stand part of the Bill.

Hospital and Special Services

On Clause 3 Mr REID moved to amend the phrase 'It shall be the duty of the Secretary of State to provide throughout Scotland by substituting the words "secure the provision" for the word "provide"'. He said this Clause dealt with services necessary to meet all reasonable requirements in hospital accommodation, medical, nursing, and other services required at or for the purpose of hospitals, and the services of specialists whether at hospitals health centres, or elsewhere. The manner in which these services were to be provided was by direct supervision of the Secretary of State. Yet Clause 2 provided alternative methods whereby the services under the Bill were to be provided either by the Secretary of State or by his securing effective provision of them. Would Mr Westwood not leave other bodies to provide hospital services where they did this at present in a perfectly good manner or where they could do so? The phraseology came from the English Act about which Mr Bevan had declared that he could not be responsible for adequate provision of services unless he was directly responsible for every detail of those services. Mr Reid was sure Mr Westwood would not try to repeat that argument. Why should local authorities who were carrying on a good hospital service be deprived of their hospitals simply to get a uniform regimentation of the hospitals of Scotland? Why should the great infirmaries which provided as good hospital services as any in or out of Britain be taken over by the Government? If the Secretary of State desired to provide additional beds himself nobody would seriously object and he was setting up under this Bill Regional Boards which were appropriate bodies to see to the proper co-ordination of hospital

services. Indeed, the Bill put too much on the Regional Boards and made it more difficult for them to carry out their primary function of co-ordinating the hospital services. That could be done at least as well if the Regional Boards did not have direct responsibility for the everyday administration of hospitals. He hoped Mr Westwood would agree to alternative methods and that either he should provide or that others should provide these services.

Mr WATSON said the local authorities had been pushed into the background even with regard to management of the hospitals. He agreed that all hospitals should be brought under a central control no matter how well they had been run in the past, but when it came to management he thought the local authorities should be given more say.

Mr CARMICHAEL said it was not merely a case of taking away the administration of tuberculosis hospitals and of infectious diseases hospitals from the local authorities but of breaking the link with the medical officer of the area and with the people responsible for reporting infectious diseases. Parliament was denying the medical officer the right to keep contact right up to the hospital.

Mr WESTWOOD said the Government deliberately avoided putting into Clause 3 the words 'to secure the provision of hospital services' and he had not the slightest intention of being accommodating so far as this particular amendment was concerned. He could not accept the arguments in favour of local authorities continuing to provide the hospital services as they did now. Some were wealthy and had been able to do the job well, but they had to consider the effectiveness of the service that had to be provided for Scotland as a whole. The national responsibility for this service must rest with the Secretary of State and it must be a national hospital service. There must be neither local authority nor voluntary hospitals but a clear national responsibility for the hospital service. He advised his supporters to oppose the amendment.

Col ELLIOT said the Opposition conceded the point made by Mr Westwood that he must have the right to provide. They were willing to modify their amendment but they asked why the Committee should not use the words employed by Mr Westwood on an earlier Clause—to provide or secure the provision of.

The Committee then adjourned.

Services Secured and Provided

Consideration of the amendment to Clause 3 moved by Mr J. S. C. Reid was resumed by the Committee on Jan. 30. Col ELLIOT said that arguments had been advanced to show that the services should be secured as well as provided by the Secretary of State. The suggestion that a great improvement would take place in the health services if they were provided by one Minister was not borne out by practical experience, for example of the pensions Ministers. For one complaint which any M.P. had during the twenty years between the wars about voluntary hospitals or about local authorities they had a hundred about the hospitals of the Ministry of Pensions. Provision of services by the alternative methods of the voluntary hospital and of the local authority hospital should not be scrapped without more justification than had been given. The Secretary of State, with his own hospitals, would be in a position to supplement deficiencies to fill any gaps and if necessary to act as a pacemaker to the hospital system which at present existed.

Mr MACLEAN WATSON said Col Elliot was trying to introduce prejudice into the debate because there was feeling about the Ministry of Pensions hospitals. As far as Mr Watson knew the Ministry of Pensions hospitals did good work during the war and had done so since the end of the war. The Ministry of Pensions hospitals might carry on under that Ministry in the future as they had done in the past.

Mr SOMERVILLE HASTINGS said it was common grounds that some power must tell each hospital what its function should be, decide what type of work it could do best and not allow every hospital incomplete facilities to undertake every type of work. The Secretary of State could not control these hospitals merely by a monetary grant. Control could not be achieved without ownership. Some small voluntary hospitals which had been highly endowed had neither the staff nor the equipment to turn out the best work. The Secretary of State could now say to such a hospital 'In the new scheme your sphere is not to be a general hospital but a convalescent home.'

Cmdr GALBRAITH said the Committee was concentrating too much on hospitals and forgetting that the clause also dealt with medical nursing and other services.

Mr BUCHANAN said the Ministry of Pensions hospitals taken on the whole compared more than favourably with most other hospitals. It was true that Members received some complaints, but if a person had a complaint about a voluntary hospital he

could write to no one because no public body had any responsibility. It was essential to the Bill that the Secretary of State should have the whole of the hospitals within his power and control. Major LLOYD said the view expressed by the Opposition was that of the majority of the people of Scotland. The amendment proposed by Mr Reid was rejected by 27 to 12.

Medical Education and Research Facilities

The chairman, Mr MATHERS then called an amendment by Mr Reid to leave out subsection 2 of Clause 3. This subsection provides that it shall be the duty of the Secretary of State in furnishing hospital and specialist services to make available such facilities for undergraduate and postgraduate clinical teaching and research as he considers necessary to meet all reasonable requirements.

Mr REID said this amendment covered narrower ground compared with others which would appear later suggesting that the teaching hospitals might receive rather different treatment from the ordinary hospitals. The Opposition thought that the difference made in the English Act between the governors of a teaching hospital and the board of management of an ordinary hospital. He did not think that all the issues raised on the functions of the teaching hospitals could be covered in an omnibus discussion. There was the relationship of the teaching hospitals with the universities the question whether the internal administration should be under the Regional Board, the position of the officers of the hospitals and whether they should be officers of the Royal Infirmary or of the South-Eastern Region, and a number of other questions. Every one of these questions was of great importance to Scotland. Mr Reid then moved to leave out subsection 2. He said that if Scotland was to have a flourishing school of medicine, it must have intimate and friendly relations between the university and the hospital in which clinical teaching took place. These relations must be between equal partners and between people who were on the spot. In the past one of the elements leading to the success of the Scottish schools of medicine had been the friendly relationship between the royal infirmaries and the universities concerned. A similar basis had been maintained as far as possible under the English Act. But in Scotland the permanent officials sitting in St Andrew's House would advise the Secretary of State on the clinical teaching facilities considered necessary to meet reasonable requirements. The Secretary of State and his permanent officials were not the right people to dictate to the universities of Scotland what clinical teaching facilities they ought to have. If the Bill went through in its present form he would view with apprehension the future of Scotland as a resort for foreign students for the teaching of students but he had told the House that the present Scottish education system was bad and ought to be altered as soon as possible so as to decentralize it. The Opposition thought the proper course was to decentralize this matter.

What the Opposition proposed was that the schemes which regional boards must make with regard to future organization of the hospital services should specify those hospitals which were to be concerned in the provision of facilities for teaching and research. It was not easy to say what was a teaching hospital. Therefore an improvement on the English scheme would be to let the regional board say which hospitals were to be chiefly engaged in teaching and which hospitals were only engage in teaching to a minor extent. The regional board knew the local circumstances and so could say which were to be the big teaching hospitals in Scotland in future. At present there were five large ones about which no one could have any doubt. Others were already used to a considerable extent for teaching and would probably come into this category. Others were only used to a minor extent and could be left out. This was a proper job for the regional board to undertake. One of the blots on the present scheme was that the new boards of management for the Royal Infirmaries in Edinburgh and Glasgow the Western Infirmary and the other big infirmaries had no direct contact with the universities. It was completely subject to the regional board. Under this Bill there was no difference in status between the board of management of a great royal infirmary and the board of management of two or three cottage hospitals in the country. Parliament would not secure the right people on the boards of the royal infirmaries if they were to be tied hand and foot.

Universities and Teaching Hospitals

Sir JOHN GRAHAM KERR said the interrelation of the university and teaching hospital was important to the welfare

of the whole public health service. The two were inextricably entangled. He instanced the calling of one of his staff by a Colonial Government to go out and tackle an epidemic of dysentery. That man was a member of a particular university staff which the outsider would think had nothing to do with such a problem. It was in the medical school of a university or an extramural medical school that such work was done. The Committee should not forget that Scotland had some of the greatest extramural medical schools in the world, such as Anderson College in Glasgow. Research was done partly in the laboratory of the University or of the medical school and partly in the wards of the infirmaries. To ensure that these two were properly run there must be an intimate relationship between the governing bodies of the university or medical school and of the teaching hospital or the result would be disaster. What would have happened to Lister when doing his research in the Royal Infirmary of Glasgow if that infirmary had been under the control of any Government official at a distant point? That great work would have been lost.

Mr SCOLLAN pointed out that the Clause itself said that as far as practicable each area must be such that provision of the services in the area could be conveniently associated with the university having a school of medicine and that the Secretary of State should consult such bodies and organizations as appeared to him to be concerned.

Mr NIALL MCPHERSON said that under the Bill a man would have the right to go to hospital and to refuse to be examined for clinical study. He asked whether the Secretary of State would have a right to say that such a man should be examined. He saw no other object in the Clause because in the past the arrangements between the universities and the governing bodies of the hospitals had worked perfectly well.

Dr STEPHEN TAYLOR felt that the English Act had a considerable advantage over the Scottish Bill in the way it treated its teaching hospitals. One desired to give the rebel in medicine the maximum opportunity for developing himself free from any supervision. However the Secretary of State must consider the size of the medical labour force which he would require in future. He must make a decision on how many people he needed in the medical school and how much clinical teaching. He must keep the subsection so that he could say how much of his hospital service was to be devoted to supplying clinical material for teaching. He had heard it said that one of the troubles which had developed of late years in the Edinburgh School of Medicine was that it had become so popular in many parts of the world and so many people had come to Edinburgh that the ratio of students to clinical teaching in the Royal Infirmary had become increasingly unsatisfactory. The regional board might not be a desirable body for nominating teaching hospitals. The Secretary of State must take a nation-wide view in deciding.

Major LLOYD said more doctors were sent out of Scotland than were provided inside Scotland. The matter was one of world-wide importance and the amendment should be considered sympathetically.

Expanding the Teaching Hospitals

Mr BUCHANAN said the Bill did not affect teaching at all. Teaching remained a duty of the university. The Government provided facilities for teaching but did not interfere with the historic privilege of the universities to provide the teaching. On this issue the local authorities the British Medical Association, and the universities were broadly agreed. The only body which was against this scheme for Scotland was the British Hospitals Association. That was the only section which would not be concerned with the running of this scheme. In Scotland the teaching hospitals played a much larger part in the provision of beds than was played by similar hospitals in England. Mr Reid had spoken of the Royal and the Western Infirmary in Glasgow and the Royal Infirmary in Edinburgh as hospitals in Scotland. That was wrong. In Aberdeen for example nearly the whole of the hospital beds for that town were provided in teaching hospitals. How could these hospitals be taken out of the scheme when they provided a greater part of the accommodation for the people? Mr Buchanan hoped to see the teaching hospitals expanded. Doctors in ordinary practice would be required to take part in teaching work. Instead of four or five grandiose hospitals in Glasgow or Aberdeen, he wished teaching hospitals to be extended to other parts of the country. He looked forward to seeing the Falkirk hospital become a teaching hospital. Under the scheme proposed there would be discussions between the regional board and the teaching hospitals to decide who was to do substantial teaching. If another hospital such as the one at Falkirk came under the regional board that board would fight to the death to keep it, and before it could be classified as a teaching hospital

it must go to the board and start a series of arguments. The Government proposed to give the universities representation on every board of management and imposed the condition that if there was a substantial amount of teaching the university should have a larger representation. The Government went further and said that the staff should be represented on the board. These proposals were more far-reaching than the English ones.

Mr THORNTON-KEMSLEY said Mr Buchanan had been less than fair to the British Hospitals Association Scottish Branch. He ought to know that that Association agreed in what was proposed and thought that the Opposition went too far in suggesting that teaching hospitals should be taken out of the regional association.

Col ELLIOT said the point in debate was not a political one. The Opposition found itself in this position because the Government were speaking with two voices. He did not think that the English solution of the problem would completely remove the difficulties, but he thought that the proposed solution in the case of Scotland would not do so either. If the university found itself in conflict with the hospital and bed accommodation was not provided for the university nominee the university professor would be in the greatest difficulty. By 34 votes to 18 the Committee decided that subsection 2 should stand part of the Clause.

On the motion that Clause 3 stand part of the Bill Mr RANKIN asked whether in the term 'specialists' Mr Buchanan included medical auxiliaries or if he proposed to cover the position of these people by Regulations as had been done in the English Act.

Mr BUCHANAN said he would endeavour to obtain an answer to this question. He remarked that owing to the terribly cold conditions in the Committee room he desired to adjourn the discussion shortly. In reply to Miss HERBERTSON he said that the department would have power to provide travelling costs to beneficiaries under the Bill. The specialist services would be available as part of the equipment of the hospitals. He promised to look into drafting amendments which had been suggested by Sir JOHN GRAHAM KERR.

The Committee then adjourned.

Food Rationing for Invalids

Col STODDART-SCOTT asked on Jan 29 the number of individuals with medical qualifications who sit on the Food Rationing (Special Diets) Advisory Committee, how many times they met during the last six months of 1946, and how many medical men were present on each occasion. Mr STRACHEY said applications for special rations for individual patients were not taken to the committee as a whole but were sent by the secretary to at least two members of the committee, the two members most qualified to deal with the particular case. All cases raising a new point were sent to all members of the committee. This was more expeditious than attempting to convene the committee to deal with each application. The full committee met when a change of the scales of extra rations automatically available for each illness was in question. For this purpose the committee met twice during the last six months. Eight of the ten members were present at the first and nine at the second meeting. He thought it satisfactory that men who were best qualified should be consulted in the case of each particular interest (see also pp 227 and 230).

Medical Students from Nigeria

Mr CREECH JONES said on Jan 29 that 381 students from Nigeria were studying in universities and medical schools in the United Kingdom. Except in the case of medical schools where the pressure was greatest the Nigerian Government did not send over priority lists. Of the eleven students from Nigeria who were placed in medical schools in 1946 three figured high in the priority list for that year. The remainder had been recommended in previous years but could not be placed for various reasons. Every effort was being made by letter and personal contact with university and other authorities to persuade them to allot as many places as possible to students from the Colonies. Mr Creech Jones praised the help they had given to the Colonial Office despite their own difficulties. He added that the situation of all institutions of higher education would owing to the claims of ex-Service students be as difficult as it was in 1946-7.

Tuberculin Tests—In 975 000 tests of Attested cattle made in 1946, 461 animals reacted and in 368 000 tests of T.T. cattle 674 animals reacted. In giving these figures on Jan 27 Mr TOM WILLIAMS added that reaction to the tuberculin test did not imply infection in the milk of a reactor.

Universities and Colleges

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a meeting of the College held on Jan 30 the following resolution was passed. The College desires the Negotiating Committee to enter into discussions and negotiations with the Minister on the Regulations authorized by the National Health Service Act.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Monthly dinners will be held in the College for Fellows and Members of the College, members of the associations linked to the College through the joint secretariat, and their wives and guests on Wednesdays at 7 p.m., Feb 12, March 12, April 9, May 7, June 11 and July 9, at an inclusive charge of £1 1s, which must be sent with the application to the assistant secretary of the College at least a week before the date of the dinner.

Geoffrey H. Bourne, D.Phil., D.Sc., has been appointed to the Readership in Histology tenable at the London Hospital Medical College and not Geoffrey Bourne, M.D., F.R.C.P., as announced in the *Journal* of Feb 1 (p. 204).

Medical News

The next meeting of the Zoological Society of London for scientific business will be held on Tuesday, Feb 11, at 5 p.m.

A joint meeting of the Royal Society of Medicine and the Scientific Film Association will be held at 1, Wimpole Street, London, W., on Wednesday, Feb 12, at 4 p.m., when the general subject for discussion will be 'The Use of Filmstrip in Medical Teaching.'

A meeting of the Royal Sanitary Institute will be held at 90 Buckingham Palace Road, S.W., on Wednesday, Feb 12, at 2.30 p.m., when there will be a discussion on 'Recent Advances in the Treatment of Sewage by Biological Filtration' to be opened by Dr B. A. Southgate.

A lecture on 'Some Chemical and Pharmaceutical Aspects of Anaesthesia' will be given by Dr H. Davis before the Pharmaceutical Society of Great Britain (17, Bloomsbury Square, W.C.) on Thursday, Feb 13, at 7 p.m.

A joint meeting of the Tuberculosis Association with the Section of Anaesthetics of the Royal Society of Medicine will be held at 26, Portland Place, London, W., on Friday, Feb 14, at 3.30 p.m. when there will be a discussion on 'Anaesthesia for Major Thoracic Surgery in the Tuberculous,' to be opened by Mr A. L. d'Abreu, Dr I. W. Magill, and Dr Joan Millar.

The Ministry of Supply announces that a further disposal sale will be held at the Ministry's Depot No. 83, Otley, on Tuesday, Feb 11, and will include a quantity of medical equipment, namely: first aid haversacks, A.R.P. first aid boxes, a surgery box, bandages, absorbent gauze, plain wound dressings, calamine lotion, surgical scissors, forceps, white basins, splints, stretchers, and tourniquets. Further information and catalogues can be obtained from the auctioneers, Messrs Daere, Son, and Hartley, Station Road, Otley (Tel. Otley 2251).

Dr A. C. Monkhouse, Deputy Director of Fuel Research, speaking on Jan 15 at the Royal Institute of Chemistry, said that about 2.3 million tons of smoke were produced in Britain every year—one half of that from domestic grates. Pollution by oxides of sulphur amounted to about 5 million tons per year, of which one fifth came from domestic fires burning raw coal. The Atmospheric Pollution Research Committee of the Fuel Research Board was investigating the problem and had developed apparatus being used by local authorities. More efficient appliances and the use of smokeless fuel would reduce domestic smoke, but no satisfactory method of reducing sulphur dioxide pollution had been developed.

A circular from the Ministry of Health points out that streptomycin is not yet generally available in Britain, but clinical trials are being carried out by the Medical Research Council, and it repeats the warning given in our annotation (Dec 14, 1946, p. 906) that in the small number of patients with tuberculous meningitis whose lives have been prolonged by treatment with this drug permanent mental derangement, blindness, or deafness has nearly always ensued.

A British medical commission headed by Lord Moran is visiting Nuremberg to study the results of experiments carried out by German scientists on the inmates of concentration camps.

INFECTIOUS DISEASES AND VITAL STATISTICS

No 3

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan 18

Figures of Principal Notifiable Diseases for the week ended Jan 18

London (administrative county) (a) England and Wales (London included) (b) Figures of Births and Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases / a blank space denotes disease not notifiable or no return available

It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct 26 Nov 2 9 16 23 30 Dec 7 14 21 28 1946 Jan 4, 11, and 18, 1947

EPIDEMIOLOGICAL NOTES

Measles and Influenza

The two conditions which are of the greatest epidemiological interest at the moment are measles and influenza. Both are the subject of leading articles elsewhere in this issue (see pp 225 and 226).

Measles was epidemic in 1945 and a comparison of the notifications in the 126 great towns for the first four weeks of this year and the two preceding years is interesting.

	1st Week	2nd Week	3rd Week	4th Week
1945	11 947	10 979	12 054	12 941
1946	771	777	726	907
1947	10 823	10 223	11 087	11 671

Influenza is not notifiable, but a comparison of the recorded deaths from influenza in the 126 great towns in the first four weeks of this year and the two preceding years gives no indication of a major influenza epidemic.

	1st Week	2nd Week	3rd Week	4th Week
1945	55	72	56	87
1946	123	165	174	273
1947	36	74	85	92

Discussion of Table

In England and Wales the common infectious diseases of childhood were more prevalent. There were increases in the notifications of measles 864, whooping-cough 264, scarlet fever 168 and diphtheria 24. The only decreases in incidence were acute pneumonia 41 and dysentery 15.

The largest increases in the notifications of measles were Warwickshire 279, Lancashire 224, Sussex 127, and London 87. The largest decreases were recorded at Durham 104 and Nottinghamshire 74. The rise in cases of whooping cough was most pronounced in the northern section of the country, notably in Yorkshire West Riding 57 and Lancashire 42. A small rise in the incidence of scarlet fever was recorded throughout the country and the only increase of any size was slightly in the south and rose slightly in the north.

There were 19 cases of dysentery in Lancashire, Preston R D compared with 8 in the preceding week and 5 further cases of dysentery were recorded in the outbreak in Hertfordshire St Albans R D, where 24 cases were notified last week.

In Scotland a decrease occurred in the notifications of measles 169 and acute primary pneumonia 42, while rises were reported for whooping cough 23, diphtheria 18 and scarlet fever 10.

In Eire a rise occurred in the incidence of measles 27, diphtheria 22, and diarrhoea and enteritis 11, decreases were recorded for whooping-cough 21 and primary pneumonia 11. The rise in cases of diphtheria was mainly contributed by Cork, Kanturk R D where an outbreak involving 10 persons was reported. Whooping cough declined in Dublin C B by 24 cases, but a fresh outbreak with 16 cases was reported from Louth, Dundalk U D.

In Northern Ireland the outbreak of measles in Belfast C B flared up, the notifications rising from 755 to 889.

Health of Glasgow

The birth rate in Glasgow during 1946 was 22.4 per 1,000, the highest rate for twenty years. The infant mortality was 67 per 1,000 births and was one below the record low level of the preceding year. The general death rate was 13.8 per 1,000 being 0.7 higher than last year. The principal causes of death were pulmonary tuberculosis 1,173, pneumonia 709, influenza 161, and other respiratory diseases 505. These were 95, 161, 115 and 64 respectively in excess of last year's totals. There were 39 deaths attributed to diphtheria, 7 more than in 1945. Deaths from infantile diarrhoea and enteritis numbered 296, compared with 396 in 1945 and 698 in 1944.

Week Ending January 25

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,286, whooping cough 2,151, diphtheria 247, measles 11,671, acute pneumonia 1,270, deaths from influenza in the 126 great towns numbered 92.

The complementary treatments for colds

THE therapeutic properties of both Silver Vitellin and natural levorotatory Ephedrine are well known. In Argotone they have been successfully combined into a stable solution in normal saline providing disinfection and decongestion in the treatment of nasal affections.

In the common cold there are other distressing features—headaches, stiffness and fever. To relieve these symptoms the oral administration of Deltamin tablets is recommended.

Together, Argotone and Deltamin offer a complementary treatment for the common cold.

ARGOTONE + DELTAMIN NASAL & EYE DROPS TABLETS

FORMULAE

ARGOTONE: Silver Vitellin 1%, Ephedrine 0.9% in Normal Saline.
DELTAMIN: Aspirin 7.70 grains, Ephedrine hydrochloride 0.30 grains.

Ideas go into action. Landmarks in medical science are not reached every day. But what men of genius discover, men of vision strive constantly to perfect—and their ideas go into action with the help of The British Oxygen Company Limited, whose task it is to see that medical equipment does not lag behind medical knowledge and that as the uses of medical gases are developed so are the means perfected of putting them to every day use.

The B.O.C.'s contribution is great for many reasons: among them the almost limitless scope of its industrial resources, the vigour of its quest for new and better methods, and the hand-in-glove co-operation it has long enjoyed with the world of medicine.

ANACARDONE

Trade Mark

(NIKETHAMIDE B.P.)

Nikethamide has been recommended for use in the treatment of various forms of circulatory collapse, specifically those associated with diabetic coma, acute bronchitis, alcoholic poisoning, and anaphylactic and serum shock. In these, as in many of the most important indications for nikethamide, it is essential to have the drug at hand for immediate use.

Nikethamide is available for clinical use as Anacardone which is issued in solution for injection (Injection of Nikethamide B.P.) and in 25 percent solution, flavoured, for oral administration. Further details are available on request.

Pharyngitis and Tonsillitis

effective therapy with ARGYROL

ARGYROL has proved its value for controlling infections of the nose and throat. Many eminent authorities have noted that the best results are obtained when ARGYROL is specified in all prescriptions.

There are sound chemical and physical reasons for this. The silver in ARGYROL is in a much finer state of colloidal dispersion also there is a far greater degree of Brownian movement, which logically must result in greater therapeutic activity. This is not true of ordinary mild silver proteins for ARGYROL is the only silver salt that does not tend to become irritating with increased concentrations. SPECIFY ARGYROL IN ALL PRESCRIPTIONS

BRIDGING THE GULF

IN ARTIFICIAL
FEEDING

For more than forty years COW & GATE Milk Foods have successfully bridged that dangerous gulf in infant feeding when breast feeding is impossible or inadequate and the child's delicate digestion needs especial consideration.

Normally medical opinion in such cases directs that a baby should be introduced to artificial feeding by means of a half cream milk.

COW & GATE HALF CREAM MILK FOOD bridges the gulf between breast and full artificial feeding. The transition period may be artificial and Cow & Gate Half Cream provides a most satisfactory means of introducing complementary feeding. Should immediate change to full artificial feeding be necessary Half Cream Food ensures a minimum disturbance of infant metabolism.

THE FOOD IS FORTIFIED BY THE ADDITION OF VITAMIN D 320 I U. per OUNCE AND IRON 1 mgm per OUNCE.

Particulars of this and other Cow & Gate preparations for specialised infant feeding, will be gladly forwarded on request.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Sodium Morrhuate Injections

Q—In two patients with varicose veins injections below the knee of 2 ml of 5% sodium morrhuate were followed by a fainting feeling, pain in the ankle and severe headache. What is the explanation?

A—The Council on Pharmacy and Chemistry of the American Medical Association recommended withdrawal of the 10% solution of sodium morrhuate from accepted remedies (*J Amer med Ass* 1942, 119, 498). This was on the basis of reports of ill effects from use of the 5% solution and much more marked ill-effects from the 10% solution. Dale, M. L. (*J Amer med Ass* 1937 108 718) reported the sudden development of vertigo, faintness, bradycardia, and cyanosis of the extremities without anaphylactic symptoms after injection of the 5% solution in a case which had received repeated injections previously. He considered the reaction specific and attributed it to idiosyncrasy. The symptoms were not anaphylactic in nature and there was no period of cessation of treatment during which the patient could have become sensitive. Previous reports of ill effects following sodium morrhuate injections for varicose veins had been attributed to anaphylaxis. K. M. Lewis (*J Amer med Ass* 1936 107 1298) found urticarial rashes at the site of injection and sometimes severe allergic reactions followed by collapse. During a first course of treatment there seemed to be no reactions but after an interval anaphylaxis occurred. He concluded that people subject to allergic disease should not receive sodium morrhuate at all.

Similarly G. A. Holland (*Canad med Ass J* 1939, 41 262) reported three severe cases of allergic reactions following the drug—nausea, cyanosis, fainting and severe shock occurring with the first dose of sodium morrhuate after an interval in treatment. The lesson is one of caution in the use of the mixture of saponified fatty acids of cod liver oil known as sodium morrhuate at the beginning of treatment but especially in patients who have received the same solution previously after a sufficient time has elapsed to allow for the development of a foreign protein sensitivity. It is recommended that the initial dose should be 0.5 ml and that after an interval in treatment an intradermal test be made. P. Clarkson (*Lancet* 1938 2, 69) states: "Sodium morrhuate is the least harmful of sclerosing agents but 5% of cases have morrhuate sensitivity." There may be immediate and profound collapse more often there is a diffuse eczematoid skin reaction which lasts two to four weeks and itches intensely. Prayer, L. L., and Becker, S. W. (*J Amer med Ass* 1935 104 997) found that 7 out of 176 patients treated with the drug had reactions mostly urticarial not necessarily at site of injection. One had weakness for two days. The protein content of a 20 ml sample was too small to be determined but the total nitrogen was 0.037 g/litre assuming that it is all protein nitrogen the protein content would be 0.25 g/litre—not enough to produce sensitization. But sodium morrhuate may act as a hapten and sensitize susceptible individuals. The eventual production of a nitritoid crisis in one patient emphasizes the desirability of changing the nature of the drug used for injecting varicose veins at the first sign of hypersensitivity.

Death from Cocaine or Adrenaline

Q—A girl of 17 received an injection of 1% cocaine in the femoral solution. She collapsed and died. Subsequently it was discovered that the solution had been made up in error with 1:1000 instead of 1:10,000 adrenaline. It is estimated that 11 to 21 mg. was injected. What is the bearing of this large dose of adrenaline on the cause of death which had been certified as an idiosyncrasy to cocaine?

A—If as much as 2 ml of the solution was injected the amount of cocaine received by the patient was 20 mg., and

toxic symptoms (though not death) have been recorded from this amount on previous occasions. It is not possible to be sure what bearing the large dose of adrenaline had on the effect of the cocaine. The cocaine might have arrested the heart by prolonging the refractory period and depressing conduction. This effect is antagonized by adrenaline, which shortens the refractory period. Cocaine usually causes convulsions as its chief toxic effect, but as there is no mention of this it presumably did not occur here. Cocaine appears sometimes to arrest the respiration by a curare-like action on the endings of the motor nerves, this action is also antagonized by adrenaline. On the whole, if the death was due to cocaine, the large dose of adrenaline would lessen the likelihood of death occurring.

Was death due to the large dose of adrenaline? It is unlikely that this dose would produce death by an action on the cardiovascular system of a girl of 17. This might occur in a woman of 47 or older, but not in one whose heart and vessels were presumably healthy. Adrenaline in a large dose may however arrest the respiration, causing apnoea, and its effect would be intensified and prolonged by the cocaine. On the whole this seems the most probable explanation of the death. This case is an illustration of the danger of using cocaine for injection. It should be used only in the eye or for superficial application to mucous surfaces.

Legality of Intrauterine Contraceptives

Q—It would be of interest to have an authoritative opinion as to the legality of the gold wishbone and Gräfenberg ring contraceptive appliances. They would appear to permit fertilization of the ovum and then either prevent subsequent implantation or (Nov. 9 1946 p. 721) act by inducing early abortion. Since presumably a woman is pregnant at any time following fertilization of the ovum it would appear that any interference after this moment except on therapeutic grounds is an offence against section 58 of the Offences against the Person Act 1861. This statute also makes it an offence to administer any noxious thing with intent to procure a miscarriage even if the woman is not pregnant. This might be held to include the fitting of such an appliance before there was any chance of a pregnancy having occurred.

A—On the purely legal side, if a woman were prosecuted for the use of such an appliance the Crown would have to prove that she had been pregnant and had miscarried through using the appliance. The difficulty is obvious. If a retailer were prosecuted the difficulty would be less because the Crown would have to prove only that he had supplied the appliance with intent to procure miscarriage. Proof could only be given however, by medical evidence that the action of the appliance was to induce abortion and unless this evidence convinced the jury beyond reasonable doubt the accused could not be convicted. As the evidence must be largely speculative, the prosecution would not be likely to succeed.

Treatment of Post-operative Thrombo-phlebitis

Q—Nine days after operation for a leaking luteal cyst a woman aged 25 developed phlebitis of the left popliteal and femoral veins. This was treated for five weeks with absolute rest but at the end of this period the veins were still tender and oedema of the leg and thigh was still pronounced. The phlebitis then spread to the right femoral vein with marked oedema. Tenderness of the lower abdomen has been constant throughout but that over the femoral and popliteal veins is now only slight. Please advise as to prognosis and further treatment.

A—The sudden extension to the right leg is thought to be due to the clot extending up to the confluence of the common iliac veins and might have been prevented by dicoumarol treatment started at the first sign of thrombosis especially as the patient was so young for this condition possibly an injection of the lumbar ganglia at the same time would have been valuable. The prognosis is good as regards life such a case is unlikely now to have a pulmonary embolism. The legs however will have a disorganized venous circulation for life, and will swell and may become eczematous and ulcerated in the usual situations possibly after a lapse of as long as twelve

or more years. To prevent these sequelae the patient should be advised to wear leg supports when she gets up—elastic bandages at first, and stockings later when the tendency to swell is less marked. Immediate treatment with dicoumarol should be started, 300 mg on the first and 200 mg on the second and third days, with an estimation of the prothrombin time on the fifth day, and the drug should thenceforth be administered with the object of maintaining for six weeks a 120% increase in the prothrombin time. The patient should get up when swelling in both legs has subsided, and 'elastoplast' or Unna's paste bandages should be worn from the knee down for the first month.

Antisymphilitic Treatment in Pregnancy

Q—Should a previously infected woman receive antisymphilitic treatment throughout each pregnancy regardless of negative Wassermann reactions in order to avoid the possibility of producing a congenitally syphilitic child? In view of the large numbers of men who have contracted this disease while in the Services what risk is there of one of these men now pronounced cured fathering a congenital syphilitic child?

A—A woman who has been infected with syphilis should invariably receive antisymphilitic treatment during each subsequent pregnancy even if her blood shows a negative Wassermann reaction because (1) such a test is not in itself proof of cure, (2) she may infect the foetus if she still harbours spirochaetes however old her infection and however much previous treatment she has had, and (3) the inconvenience of treatment is as nothing compared with the tragedy of producing a syphilitic baby.

A man who contracted syphilis while in one of the Services who was treated (adequately) and pronounced cured is extremely unlikely to father a congenitally syphilitic child because it would be necessary for him first to infect his wife, this is improbable not only because he has been treated and has passed tests of cure but also because the older the husband's infection the less likely is it to be conveyed to the wife, after two years a man is unlikely to be contagious, and after four years is almost certainly not so assuming he has been symptom-free for those periods. This latter applies when treatment has not been given and still more so when it has, most Service men were treated very adequately during the war, in fact probably much more so than they would have been had they been civilians.

It is hardly correct to speak of the large numbers of Service men who contracted syphilis during the war, in fact the numbers of British soldiers infected were relatively small, at any rate compared with other nations (See also Oct 5, 1946, p 521).

Remote Risk of Contracting Tuberculosis

Q—Is it safe for a child of 3 to stay in a house where a patient was nursed for five years with open tuberculosis and died three months before the child's visit?

A—It would be very unlikely that any harm could result from a child staying in a house three months after the death of a patient suffering from pulmonary tuberculosis, provided that the usual precautions had been taken to disinfect the mattress and bed-clothes, that the personal belongings of the patient which were in constant use had been removed and that the room had been thoroughly cleaned. The tubercle bacillus is rapidly killed by direct sunlight and it would not survive if there were good ventilation and a reasonable amount of sunlight entering the house. It is difficult to find the tubercle bacillus even in the dust from tuberculosis hospital wards so that the likelihood of contracting tuberculosis from living in a house three months after the death of a patient is remote.

Vitamin H

Q—What is vitamin H? Has it any effect on alopecia or on baldness? Is it sold under some branded name in this country?

A—Vitamin H is the same as biotin. So far as the writer is aware no work has been published on its effect on baldness and alopecia. It is not sold under branded names in this country, in fact it is still only obtainable in very small amounts

Letters and Notes

Endogenous Depression in General Practice

Dr A S ELLIS (Napsbury Hospital) writes: Many will agree with Dr A Lionel Rowson's implications (Jan 18 p 111) that conditions in some mental hospitals are far from ideal, one feels however, that Dr Rowson displays regrettable ignorance concerning present day methods of psychiatric investigation and treatment. With regard to Dr Sheldon's cases (quoted by Dr Rowson) it is a safe bet that, in the unlikely event of a magistrate's making a reception order for these patients, the organic nature of their illnesses would have been discovered during their first week in a mental hospital. Modern psychiatrists are fully alive to the possibility of organic disease, and it is not correct to say, as does Dr Rowson, that "most of the patients' complaints are invariably put down to imagination and persecution mania." Diagnostic errors such as those against which Dr Rowson inveighs would be more often avoided if general practitioners more frequently adopted the course outlined by Dr L Sheldon (Jan 4, p 33), and submitted to radiography all cases of dyspepsia of over four weeks' duration. By such ordinary precautions could the general practitioner spare his patient months of discomfort and himself the humiliation of having cases referred back by the psychiatrist with a tactfully worded suggestion that an organic investigation be carried out.

Dr WILLIAM SARGANT (Sutton Emergency Hospital) writes: Dr C A H Watts's suggestion in his article (Jan 4, p 11) that many of the less severe cases could be treated with out-patient ECT has proved correct. He mentions American work along these lines, but out-patient ECT has also been done in London hospitals since 1941. I have used it for over four years and the results have been most gratifying. Many patients have been saved months of misery and incapacity. Careful selection of cases is important. I find that in 1946 there were 113 patients referred to the out-patient ECT clinic at the West End Hospital for Nervous Diseases, of which only 45 were treated, and in 1945 the figures were 35 out of 89. The high rejection rate was accounted for in part by neurotics and schizophrenics and by those needing hospital supervision during treatment. There has been hesitation in many parts of the country in starting this method. Patients have had to travel to London from as far afield as Dorset each week for treatment to avoid admission to a mental hospital. Any risks inherent in out-patient ECT are easily counterbalanced by the tragedies involved in leaving such patients untreated. Before the war it was statistically predicted that 90,000 people living in the area of Greater London alone would eventually die by their own hand. Many such suicides are severe examples of the much greater number of depressions who suffer prolonged invalidism without mental hospital admission.

Doctors' Wives and the Act

Dr P E R KIRBY (Brighton) writes: May I suggest that when the Negotiating Committee get into action a thought might be given to that unfortunate person, the doctor's wife without domestic help. When the State Medical Service comes into being I visualize knocks at the door and rings on the telephone all day and half the night. The so-called better class State patients will not be content to await their turn in the surgery but will demand preferential treatment. As far as I can see, as the Act now stands we shall lose our practices, perhaps our homes, and possibly our wives.

Yellow Fever Inoculation Centres

The Department of Health for Scotland has arranged to set up centres where inoculation against yellow fever may be obtained free of charge by people intending to travel to or through areas where that disease is prevalent. Certificates of inoculation approved by the Government will be issued from the centres. The addresses are Dr W R Logan, Bacteriological Department, Royal Infirmary Lauriston Place, Edinburgh 3, The Medical Officer of Health, 20 Cochrane Street, Glasgow, C1, Dr J Smith City Hospital Laboratory, City Hospital, Urquhart Road, Aberdeen.

WATER AND SALT DEPLETION*

BY

H L MARRIOTT, CBE, MD, FRCP

Physician with Charge of Out-patients Middlesex Hospital

A great recent advance in knowledge has been the separation of the respective effects of water depletion on the one hand and of salt depletion on the other. The distinction seems to have been first made, through experimental work, by Kerpel Fronius (1935), and the studies of McCance (1936-1938) on salt metabolism greatly clarified the subject. In the clinical field Nadal, Pedersen, and Maddock (1941) have been pioneers. Water and salt are so closely associated in the body that for long the separate effects of their deficiencies have been confused. This has been unfortunate because it has led to wrong treatment. It is now realized that there often arise conditions of (a) pure water depletion, (b) pure salt depletion, and (c) mixed water and salt depletion. All are common and all result in dehydration, but in dehydration of two types which, as Nadal, Pedersen and Maddock have said, 'differ from each other not only in mechanism of production but also in symptomatology and treatment indicated. In fact almost the only similarity between the two conditions is that implied by the term "dehydration"'. Nadal and his associates (1941, 1942) have called the two types simple dehydration and extracellular dehydration. I have termed them primary and secondary dehydration (Marriott, 1943). It is perhaps best to get away from the word "dehydration" and speak, in terms of causation, of water and/or salt depletion.

Pure water depletion occurs when water intake stops or is inadequate and when there is no significant sodium chloride loss in secretions. The common causes are great weakness from any serious medical or surgical condition, coma of any causation and dysphagia due to local conditions. Administration of saline to patients suffering only from water deficiency makes them worse (McCance and Young 1944). Pure salt depletion arises when water and salt are lost in secretions—for example, in vomiting or diarrhoea—and water only is replaced. This situation is common nowadays when there is general consciousness of the importance of dehydration but a tendency to think only in terms of water administration and to forget that water cannot be held in the body without salt. Fluid balance in patients so treated is usually recorded on intake and output charts which at least for a time show satisfactory figures in regard to urine output. In spite of their theoretical hydration they continue to look dehydrated and go downhill. They are not thirsty and this is regarded as further evidence that they cannot really be dehydrated. Their deaths are ascribed to toxæmia or uræmia or circulatory failure when they have in fact died from simple lack of salt and

could easily have been saved. It is probably not an exaggeration to say that large numbers of patients die unnecessarily in these circumstances. On the other hand, others die from uncontrolled excessive saline administration.

Basic Physiological Considerations

The main facts relating to body water are shown in Table I and Fig. 1 (Peters, 1935, 1942, 1944, Gamble

TABLE I—Normal Content of Body Water in a Man Weighing 70 kg (11 stones)

	% of Body Weight	Litres*
Intracellular	40-50	35
Extracellular	12-18	11
Tissue fluid	4-5	3
Plasma		
Total	70	49

* The British pint = 0.57 litre the U.S.A. pint = 0.47 litre

1942, Abbott, 1946). The total salt content of the body is about 1/400 of the body weight (Bartlett, Bingham, and Pedersen, 1938). In a 70-kg (154 lb or 11 stones) man this means about 175 g, or 6 oz. Two thirds of it is in the plasma and tissue fluid, nearly all the rest is in the alimentary secretions, sweat and urine. The composition of plasma and tissue fluid is shown in Fig. 2 (Gamble *et al.*, 1923, Gamble, 1942). The great predominance of sodium and chlorine is evident. It should be observed that the composition of plasma and tissue fluid, apart from the protein in the former, is identical. Indeed these are not two fluids but the same single continuous fluid—the extracellular fluid. This conception of the continuity of the extracellular fluid is vital to understanding of the subject.

The intravascular portion of the extracellular fluid is said to lie within the 'vascular compartment'. The tissue space portion is said to occupy the 'interstitial compartment'. It must, however, be understood that there is constant to-and-fro filtration of the fluid between the two compartments. In every capillary there is hydrostatic ejection of fluid in the proximal portion while in the distal portion where the hydrostatic pressure gradient has declined, there is return of an equivalent volume of fluid under the influence of the osmotic pressure exerted by the plasma

FIG. 1—Body fluid compartments (man of 70 kg)

* The Course in Lectures delivered at the Royal College of Physicians, London, on Dec. 7 and 8, 1946. These will be published in the next issue of the Journal and will appear in the next issue.

protein molecules (Starling, 1895-6) The volume of oselating filtrate is possibly of the order of hundreds of litres daily The normal constancy of the plasma volume is evidence of the accurate balance struck between hydrostatic pressure and plasma protein osmotic pressure If it were not for the latter, a man would lose the whole of his plasma into his tissue spaces within ten seconds (Landis, 1937)

FIG 2—Composition of plasma and tissue fluid (extracellular) compared with that of intracellular fluid. The scale is graduated in milliequivalents per litre of water (= milligrammes per litre - atomic weight \times valency)

The back-and-forth movement of fluid between the vascular and interstitial compartments facilitates exchange of substances, so that the tissue fluid is maintained constant in all its properties. According to the concept of Claude Bernard the tissue fluid is the "internal environment" of the cells and the reason for the evolution of multicellular organisms wherein cells are assured of existence in a medium far more constant than the cells of unicellular or few-celled organisms can count upon from the external environment. Intracellular fluid is of quite different composition from extracellular fluid (see Fig 2) and is practically devoid of sodium and chlorine except for the small amount of the latter in red blood cells (Laviates, D Esopo, and Harrison, 1935)

The distribution of water between cellular and tissue fluids is determined by their relative osmotic pressures, since cell membranes are freely permeable to water (Darrow and Yannet, 1935). Osmotic isotonicity of the tissue fluid is perhaps the most important of all the properties in regard to which constancy is required by the cells. Any osmotic imbalance must result in water being either sucked out of the cells or forced into them. In the osmotic equilibrium between intracellular and tissue fluid it is the electrolyte ions which play the chief part. In cell fluid the main ions are potassium cations and phosphate anions, in the extracellular

fluid osmotic pressure is mainly exerted by sodium cations and chlorine and bicarbonate anions. The sodium ions are the most important because there is no substitute for them. Any lack of chlorine ions is automatically filled by bicarbonate ions, which are always freely available from tissue metabolism. The osmotic relationship between the body-fluid compartments is shown diagrammatically in Fig 3. The dividing septa—the capillary and cell mem-

Osmotic Difference between Water and Salt Depletion

The difference between these conditions is shown diagrammatically in Fig 4, it depends on the fact that the respective depletions produce opposite effects on extracellular fluid osmotic pressure. In simple water lack the extracellular fluid becomes hypertonic because water is lost from it, through the lungs, skin, and urine, without fully

FIG 4—Showing the osmotic pressures in (A) pure water depletion (primary or simple dehydration) and (B) pure salt depletion (secondary or extracellular dehydration)

parallel salt loss. In consequence water is sucked out of the cells and the volume of the extracellular fluid tends to be maintained. The dehydration is chiefly a matter of loss of cellular water. In salt depletion the extracellular fluid becomes hypotonic from loss of electrolytes. There is no tendency for water to be sucked out of the cells. The volume of the extracellular fluid falls because the kidneys excrete water in the attempt to maintain extracellular isotonicity. The reduction in volume is relatively greater in the tissue fluid than in plasma, because the simultaneous decline in hydrostatic pressure, together with a rise of colloid osmotic pressure from concentration of plasma proteins, determines a relative shift of fluid into the vascular compartment from the interstitial compartment. This shift, however, is insufficient to prevent marked fall in plasma volume.

Body Water Balance

Under normal conditions water intake exceeds requirements and balance is maintained by renal excretion of the surplus. Average adult intake and output figures are given in Table II. If all water intake stops, unavoidable water

TABLE II—Average Water Intake and Output in an Adult

Intake		Output	
	ml		ml
As fluid	1,500	Vaporization	1,000
As solid food	1,100	Lungs, 400	
		Skin, 600	1,500
		Urine	100
		Faeces	
Total	2,600	Total	2,600

losses continue by vaporization (through the lungs and skin), 1,000 ml, and in the form of urine (minimum), 100 ml, a total of 1,100 ml. So the body loses water at a rate of about 2% of body weight per day. Death when the loss reaches approximately 15% of body or 20 to 22% of body water—in about 7 to 10 days.

Urine Water Minimum Excretory Volume

Ordinarily, urine water consists of two parts (a) minimum volume for excretion of waste products ("obligatoire" of Ambard and Papin, 1909), and (b) surplus

water The minimum volume depends on the concentrating power of the kidneys and the amount of waste products The relation of required minimum volume to maximum attainable specific gravity is shown in Fig 5, constructed from the data of Newburgh *et al* (1932, 1933, 1935)

FIG 5—Chart to show the relation of required minimum volume to maximum specific gravity of urine

solutes, and concentration is dealt with by Gamble and Butler (1944) Diminished renal concentrating power is common It occurs in infancy (McCance, 1946), in old age, in chronic nephritis, and in other pathological conditions of the urinary tract, such as obstructive lesions—especially prostatic obstruction It also occurs as a sequel to many conditions of severe illness or 'shock' (Macgrath, 1945) Of particular relevance is that it follows

upon any episode of severe or prolonged dehydration, especially of the salt-depletion type Such episodes are often recurrent Patients who can secrete only dilute urine may need to pass nearly 2 litres (3½ pints) daily, they very readily enter the common vicious circle shown in Fig 6 It happens in many cases

FIG 6—Vicious circle due to inadequate volume of urine

A useful device suggested itself to me some ten years ago in regard to a man 80 years of age with damaged kidneys who invariably forgot to carry out instructions to drink 6 pints (3.4 litres) a day On three occasions he became uraemic and passed into the vicious circle of Fig 6 each time he was rescued by intravenous infusions After the third attack he was supplied with a large measuring cylinder with a red ring painted round it at the 2000 ml mark, and he was told to pass all his urine into it and reach the red ring every 24 hours or he would die This clear demonstration of the purpose before him plus its automatic action as a reminder achieved what exhortation had failed to do The same device using old glass

was secured an adequate output of urine from sweating soldiers on sulphamidates in hospitals in India and Burma It is especially applicable to the conditions of general practice but is also very useful in hospital work

The other factor which determines the minimum excretory volume of urine is the quantity of waste products This is relatively much greater in infants and children because of their greater metabolism It is raised in any condition increasing metabolism in individuals of any age, such as muscular exertion fever and thyrotoxicosis it is also increased in water depletion (Black *et al* 1944) It is particularly raised after haemorrhage into the alimentary tract (Black 1939 1940 1942 Chunn *et al*, 1941a and b) A severe haemorrhage from a peptic ulcer may discharge as much protein into the gut as a meal of 5 or 6 lb (2.26-2.7 kg) of meat Raised blood urea is important when dehydration enters into the picture because it produces forced diuresis (Avery Jones, 1939, Black, 1942)

Water Balance in Children

I introduce this subject with confidence as I have little personal experience However no consideration of water

and salt depletion would be complete that did not mention these states in children, in whom they are doubly important The relatively greater metabolism of infants and children causes greater loss of water by vaporization, since this is a function of energy metabolism It also, as already stated, causes a proportionately greater amount of waste products, necessitating a relatively larger minimum excretory urine volume Gamble (1942) estimates the unavoidable water losses of a 7-kg (15½-lb) infant as

Vaporization (lungs and skin)	ml
Minimum urine	200
Total	300

The total unavoidable losses for a 70 kg (11-stone) man have been put at 1,500 ml Therefore the unavoidable water depletion of an infant is proportionately twice as great and represents a daily loss of 4% of body weight Recent work showing the inability of infants to secrete concentrated urine (McCance and Young, 1941, McCance 1946) suggests that the figure for minimum urine is higher than that stated above It is evident why infants ingest so much more water, in proportion to relative body weights, in their milk than do adults from their beverages and solid food The relative amounts are between three and four times as great It is also evident why infants withstand water deprivation so badly their total store is depleted at twice, or more than twice, the rate of adults and so they die in less than half the time

Causation and Effects of Pure Water Depletion

Pure water depletion may be caused by (1) Conditions in which water is unavailable, as in the case of shipwrecked men in boats, men lost in the desert, or immobilized by injuries and unable to reach a water supply (2) Inability to swallow, due to (a) dysphagia from such causes as quinsy diphtheria, or carcinoma of the oesophagus, (b) coma of any causation, (c) great weakness In practice the last the chief cause, for great weakness may arise in any serious medical or surgical condition 'Extremely enfeebled patients cannot make their need for water effective Thirst, the normal protection against dehydration, loses its insistence, and their weak state renders the satisfaction of even such thirst as they do feel an intolerable effort They really cannot rouse themselves to the exertion of drinking a few sips and they give up and feebly shake their heads' (Marriott and Kekwick, 1937)

Knowledge of the effects of pure water depletion is derived partly from clinical observations on patients, but more precise information has come from experimental water deprivation of animals and of volunteers (Coller and Maddock, 1935, Black, McCance, and Young, 1944, McCance, 1945) Thirst is the earliest symptom and tends to be progressive (Dill, 1938) Dryness of the mouth, due to decreased salivation, soon follows and is also progressive, it may make the swallowing of dry food impossible The urine volume falls to the minimum and the urine becomes as concentrated as the renal concentrating power will allow Given normal kidneys and a normal solute load, the volume will be approximately 500 ml, the content of dissolved solids 6 to 8 g per 100 ml, and the specific gravity will rise to more than 1030 and may even exceed 1040 The kidneys are faced with the dilemma of having to attempt simultaneously to excrete waste and salt and yet to economize water Loss of weight is proportional to the water deficit Weakness is progressive but is not marked until three or four days have passed Patients look ill and their faces have a 'pinched' grey appearance Temperamental peculiarities become exaggerated Black, McCance, and Young (1944) state 'Serious people become sombre

while others, normally cheerful, exhibit a somewhat hollow vivacity. Mental power is eventually impaired and the patient may suffer from confusion and hallucinations.

The sodium chloride content of the plasma tends to rise, according to Black *et al* (1944) plasma sodium increases by 30 mg per 100 ml after three or four days. The blood urea slowly rises, though normal glomerular filtration tends to be maintained—at least up to moderately severe hydropenia (Black, McCance, and Young, 1942, McCance, 1945). Evidence of alteration in the plasma volume, so far as I have been able to discover, is scanty. There seems to be very little shrinkage of plasma volume, and consequent haemoconcentration, at levels of water depletion around 6% of body weight (Coller and Maddock, 1935, Black, McCance, and Young, 1944). It would be of great interest to know the facts in regard to the late stages. Evidence of circulatory changes is also inadequate. Water absorption is very rapid and the patient's condition improves within a matter of minutes after water ingestion.

The mechanism of death is far from being finally settled. Kerpel-Fronius (1935) and Black, McCance, and Young (1944) consider the probable cause of death to be a rise of the osmotic pressure of the body.

Quantitative Correlation of Manifestations and Deficit

Existing information permits the division of cases of water depletion into three grades:

(1) *Early*—Thirst definite but other effects not yet present. A deficit of approximately 2% of body weight, equivalent to 1.5 litres or 3 pints in a 70 kg man.

(2) *Moderately Severe (three to four days without water)*—Marked thirst and dryness of mouth, oliguria, weakness, ill appearance, slight personality changes, still capable of fair mental and physical performance. A deficit of approximately 6% of body weight (4.2 litres, or 1 gallon, in a 70 kg man).

(3) *Very Severe*—All the above manifestations with in addition marked impairment of mental and physical capacity. A deficit of 7 to 14% of body weight (5 to 10 litres, or 1 to 2½ gallons, in a 70-kg man).

Body Salt Balance

Salt balance is normally maintained in a similar way to water balance, that is, intake (average, 8 to 15 g daily) exceeds requirements and the surplus is excreted in the urine. The intake is derived from salt combined in food or added during cooking or as a condiment. Considering the importance of salt, it is odd how often official or authoritative publications omit definition of sodium and chlorine requirements from recommendations regarding dietary allowances, and also leave out of nutritional tables the amount of these elements present in various foods. This is even true in tropical countries, where salt deficiency is perhaps the commonest of all deficiency states. A most important practical point of difference between water and salt, in regard to balance maintenance, is that, whereas water intake is safeguarded by thirst, there is no similar insistent sensory warning when salt is deficient.

If neither water nor food is taken, the effects of water depletion dominate the picture because unavoidable water losses continue while salt loss, assuming no abnormal losses are occurring, is relatively slight. The body economizes salt more efficiently than water. If only intake of food ceases and water continues to be taken it is a considerable time, in the absence of abnormal salt losses, before serious salt depletion occurs. The kidneys practically stop excreting salt as soon as plasma levels fall below normal—that is, sodium, 320 to 350 mg per 100 ml or 139 to 152 meq/litre; chlorine, 340 to 385 mg per 100 ml or 97 to 110 meq/litre. Benedict (1915) in his study of Levanzin who fasted and drank only distilled water for

31 days, found sodium and chlorine in the urine to be as follows:

Period	Sodium	Chlorine
First 10 days	8.96	8.44
Second 10 days	0.89*	2.13
Third 10 days	0.59	1.57
Total	7.44	12.14

* Benedict's figures for sodium were incomplete for 4 days of the middle period. I have assumed an average for these 4 days.

This represents a total loss of less than 20 g of salt in 30 days.

Abnormal Salt Balance
